w in f's domain is a **critical number** if **either** f'(w) = 0: could look like

The First Derivative Test A critical number w is a relative max if f'(left of w) > 0 & f'(right of w) < 0; relative min if f'(left of w) < 0 & f'(right of w) > 0. Important No other critical numbers should be between w and where the sign of f' is checked! If both are positive or both are negative, then w is an

If both are positive or both are negative, then w is an **inflection point** of f.

The Second Derivative Test A critical number w is a relative min if f''(w) > 0 & relative max if f''(w) < 0.

Finding max/min on a closed interval

If f is continuous on $a \le x \le b$ then f's \max/\min values must occur either at a or at b or at a critical number inside the interval.

f has an **inflection point** at w if w is in f's domain and if the concavity of f's graph is different on either side of w:

f is **continuous** at w if $\lim_{x\to w} f(x)$ exists and equals f(w) or check $\lim_{x\to w^+} f(x)$ and $\lim_{x\to w^-} f(x)$ both exist and = f(w). f is **differentiable** at w if $\lim_{h\to 0} \frac{f(w+h)-f(w)}{h}$ exists. This is f'(w): the rate of change of f with respect to w or the slope of the tangent line to y=f(x) at x=w.

Implicit differentiation/related rates

Key point Differentiate a whole equation. Don't forget what's varying, chain rule, product rule, etc. **Example** If $xy^2 = \sin(x+y) + 3x$ then $\frac{d}{dx}$ the equation. Get $1 \cdot y^2 + x \cdot 2yy' = \cos(x+y)(1+y') + 3$. **Solve** for y'.

f defined in a < x < b has a **relative maximum** at w in the interval if $f(w) \ge f(x)$ for x's near w on both sides. f defined in a < x < b has a **relative minimum** at w in the interval if $f(w) \le f(x)$ for x's near w on both sides. Relative max and min must occur at critical numbers.

Differential or tangent line approximation

 $f(w+\Delta w) \approx f(w)+f'(w)\Delta w$. The graph's bending causes **error**: the true value is larger when the graph is concave up and smaller when the graph is concave down.

Intermediate Value Theorem If f is continuous in $a \le x \le b$, f's values include all numbers between f(a) and f(b): a continuous function's graph has no jumps. Mean Value Theorem If f is differentiable in $a \le x \le b$, there are some c's in the interval with $f'(c) = \frac{f(b) - f(a)}{b - a}$: some tangent lines of a differentiable function's graph must be parallel to any chord. Rolle's Theorem MVT with f(a) = f(b) = 0. Fund. Thm. of Calculus If F' = f then $\int_a^b f(x) \, dx = F(b) - F(a)$; $\frac{d}{dx} \int_a^x f = f(x)$.

f is **increasing** in a < x < b if $f(x_1) \le f(x_2)$ for any $x_1 \le x_2$ in the interval. If f'(x) > 0 always in a < x < b then f is increasing there.

f is **decreasing** in a < x < b if $f(x_1) \ge f(x_2)$ for any $x_1 \le x_2$ in the interval. If f'(x) < 0 always in a < x < b then f is decreasing there.

f is **concave up** if lines connecting the graph are above the graph: it bends up. If f''(x) > 0 always in a < x < b, f is concave up.

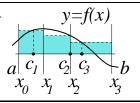

f is **concave down** if lines connecting the graph are below the graph: it bends down. If f''(x) < 0 always in a < x < b, f is concave down.

Function Antiderivative $\int f(x) dx$ f(x)Kf(x) $K \int f(x) dx$ $f(x)+g(x) \quad \int f(x) dx + \int g(x) dx$ $x^{n} \quad \frac{1}{n+1}x^{n+1} + C, \ n \neq -1$ $\ln x + C \ (x > 0)$ $e^x + C$ $\sin x$ $-\cos x + C$ $\sin x + C$ $\cos x$ $\ln(\sec x) + C$ $\tan x$ $\int f(u) du$ $\int f(g(x)) g'(x) dx$ when u = q(x) (Substitution)

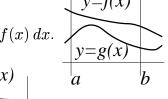

Sample points
$$\{c_1, c_2, c_3\}$$
 Partition $\{a = x_0 \le x_1 \le x_2 \le x_3 = b\}$ Riemann sum $f(c_1)(x_1 - x_0) + f(c_2)(x_2 - x_1) + f(c_3)(x_3 - x_2)$

With many sample points and small differences in the partition, the sum will closely approximate the **definite integral** $\int_a^b f(x) \, dx$.

If
$$\lim_{x\to a^{(\pm)}} f(x) = \pm \infty$$
 then $x = a$ is a **vertical asymptote** of $y = f(x)$ and if $\lim_{x\to \pm \infty} f(x) = b$ then $y = b$ is a **horizontal asymptote** of $y = f(x)$.

If
$$g(x) \le f(x)$$
 in $a \le x \le b$, $\int_a^b g(x) dx \le \int_a^b f(x) dx$.

$$\int_a^b f(x) dx + \int_b^c f(x) dx = \int_a^c f(x) dx$$

$$\int_a^b f(x) dx$$
 is **signed area**: area I – area II + area III.
