FINITE DIMENSIONAL OPEN LOOP CONTROL GENERATORS FOR NONLINEAR SYSTEMS

Eduardo D. Sontag
Department of Mathematics
Rutgers University
New Brunswick, NJ 08903

ABSTRACT

This paper concerns itself with the existence of open-loop control generators for nonlinear (continuous-time) systems. The main result is that, under relatively mild assumptions on the original system, and for each fixed compact subset of the state space, there always exists one such generator. This is a new system with the property that the controls it produces are sufficiently rich to preserve complete controllability along nonsingular trajectories. General results are also given on the continuity and differentiability of the input to state mapping for various $p$-norms on controls, as well as a comparison of various nonlinear controllability notions.

This version printed 10 July 1995.

1. Introduction

In this paper we consider nonlinear finite dimensional systems of the type

\[ \dot{x}(t) = f(x(t), u(t)), \]

where \( x(t) \) is the state, and \( u(t) \) is the control, at time \( t \). (More precise definitions are given later.) An \((1.1)\) \textit{open-loop control generator} for such a system is a new system, described by equations

\[ \begin{align*}
\omega(t) &= P(\omega(t)), \\
u(t) &= Q(\omega(t)).
\end{align*} \]

This is a system with no controls but with an output map whose values are in the input space to \((1.1)\). For \((1.2)\) any initial condition \( \omega(0) \) of \((1.2)\), there is (at least for small enough times \( t \)) a generated control \( u(t) = Q(\omega(t)) \), where \( \omega(·) \) is the solution of \((1.2)\) with initial condition \( \omega(0) \). For any initial state \( x(0) \) for the original system, this control gives rise to a trajectory.

It is often the case in systems problems that such models are used for control generation; for instance when dealing with tracking and the study of responses to ramps (polynomials of degree at most 1), one introduces the control generator with dynamics \( \omega_1 = 0, \omega_2 = \omega_1 \), and output \( u(t) = \omega_2(t) \). Different initial conditions \( \omega_1(0), \omega_2(0) \) will give rise to all possible ramps.

A natural question to ask is: if the system \((1.1)\) is known to be completely controllable, does there exist also a system as in \((1.2)\) with the following property: for each states \( x_0 \) and \( x_1 \), there should exist some initial condition \( \omega(0) \) and time \( T \) such that the control \( \omega(·) \) is well defined for \( t \) in \([0,T]\) and so that the trajectory induced by \( \omega \) on the original system takes \( x_0 \) into \( x_1 \) at time \( T \). Even more interestingly, one may ask that all these trajectories be nonsingular in the sense of optimal control, or equivalently, that the time varying linear systems obtained by linearizing along the obtained trajectories be themselves completely controllable. This last requirement is important if linear feedback techniques are to be applied in order to regulate for small perturbations along the trajectories in question.

In this paper, we provide a positive answer to the above question. Some technical conditions are imposed, some of which are probably not essential (property (*) below) and could be dropped if the proof is based on a different argument, as suggested later. Other assumptions, dealing with properties of the Lie algebra of vector fields generated by the control fields \( f(·,u) \), are unavoidable, as shown by counterexamples later.

A companion paper to the present one, [SO1], \textit{starts} with the assumption that such a control generator exists, and provides a ‘universal’ method for regulation along trajectories obtained as described above. The notion of a control generator is essential in the proofs given there, since all arguments depend on having a suitable parametrization of trajectories. Given a control generator, trajectories can be indeed parametrized by \( \omega(0), x(0), \) and \( T \). The paper [SO1] deals with "pseudolinearization" properties of nonlinear systems, in the sense of work by Rugh and Baumann ([R], [BAR]) and by Reboulet, Champetier et.al. ([RC], [CMM]). These authors have dealt with the study of families of linearizations of nonlinear systems around different operating points, and in particular the problem of obtaining compensators with the property that all closed-loop linearizations have the same dynamic behavior. In contrast, [SO1] studies linearizations along \textit{trajectories} of nonlinear systems. The basic result there, when coupled with the theorem proved here, establishes the following fact: provided that a system satisfies certain reasonable assumptions, it is possible to affect any desired state transfer using a suitable open loop signal generator, and to regulate for small deviations from the corresponding trajectories using linear control design techniques. The desired regulator has a form independent of the open-loop trajectory, which is fed on-line. An explicit form for the controller, as well as experimental results including the control of angular velocity of a rotating satellite, are given in [SO4].
Central to both the result here and that in [SO1] is a study of those trajectories of a given system along which the linearization (as a time-varying linear system) is controllable. Such nonsingular trajectories play a central role in the construction of precompensators. If a system is controllable, that is, we may go from any state to any other state, one may expect that it should also be true that one can affect transfers in a nonsingular manner. Unfortunately there is no "Sard’s theorem" in infinite dimensions (controls belong to an infinite dimensional space) that would allow such a conclusion. We shall prove however that indeed such nonsingular controllability holds, if (and only if) the given system satisfies a certain nondegeneracy property. (Roughly, there must be no periodic autonomous subsystems.) Sufficient conditions for this to happen are that there be no finite escape times and that the state space be simply connected, or that there be some equilibrium state for the system.

After setting up definitions and the statement of the main result, we provide various results dealing with the continuity and differentiability of the input to state mapping for various $p$-norms on controls. These results are needed later, but we haven’t been able to find them in the literature in the generality needed. Later we provide a comparison of various nonlinear controllability notions; these results should also be of interest in themselves. Finally, we give in the last section the proof of the main theorem.
2. Definitions and statement of Main Theorem.

A system $\Xi$ is described by a set of controlled ordinary differential equations

$$x(t) = f(x(t),u(t)), \quad t \in \mathbb{R},$$

where for each $t$, $x(t)$ is in the state space $S_\Xi$, which we take to be an arbitrary open subset of $\mathbb{R}^n$, and $u(t)$ is in the control-value space $U_\Xi$, which we take to be an Euclidean space $\mathbb{R}^m$, $m$ an integer. We assume that the dynamics map $f: S_\Xi \times U_\Xi \to \mathbb{R}^n$ is real-analytic, and that the following property holds:

(*) There is a continuous function $\beta: S_\Xi \to \mathbb{R}$ such that

$$|f(\xi,\mu)| \leq \beta(\xi) \quad \text{for all } \xi \in S_\Xi \text{ and all } \mu \in U_\Xi.$$

We often omit the argument $t$. The system is polynomial if each component of $f$ is a polynomial and rational if each component of $f$ is a rational function having no poles on $S_\Xi \times U_\Xi$. It is autonomous if $f$ is independent of $u$; autonomous systems will be used in order to model control generators.

Other definitions of system could be used. Generalizing the results to systems on manifolds would be straightforward but notationally somewhat cumbersome; on the other hand, the generalization of the results given here to smooth but nonanalytic systems would be an interesting topic for further research.

We need to define carefully the notion of control. An $u: [0,T] \to U_\Xi$ for which there is a compact subset $K = K_\xi$ of $U_\Xi$ such that $u(t) \in K$ for almost all $t$ is an admissible control; the defining property says that $u$ is essentially bounded, and $T = T_\xi$ is the length of $u$. Given any such $u$ and any $\xi \in \Xi$, the unique absolutely continuous solution $x(\cdot)$ of (2.1) with $x(0) = \xi$ at time $t \leq T$, if defined, is denoted by $x(t) = \psi(t,\xi,u)$. A pair $(x,u)$ of functions on an interval $[0,T]$, with $u$ an admissible control and $x$ satisfying (2.1), i.e., $x(t) = \psi(t,x(0),u)$ for all $t \in [0,T]$, is an admissible trajectory on $[0,T]$. If $u$ has length $T$ and $\xi$ is such that there exists an admissible trajectory $(x,u)$ on $[0,T]$ with $x(0) = \xi$, we say that $u$ can be applied to $\xi$. If there is an admissible trajectory on $[0,T]$ with initial $x(0) = \xi_1$ and final $x(T) = \xi_2$, we say that $\xi_1$ can be controlled to $\xi_2$ in time $T$, or that $\xi_2$ can be reached from $\xi_1$, and that $u$ steers $\xi_1$ to $\xi_2$. If there is some $T > 0$ such that that $\xi_1$ can be controlled to $\xi_2$ in time $T$, we just say $\xi_1$ can be controlled to $\xi_2$.

The variational system of $\Xi$ along the admissible trajectory $(x,u)$ is the linearization of $\Xi$ along this trajectory, that is, the linear time varying system $D_{x,u}\Xi$ defined as follows:"

$$\lambda(t) = f_x(x(t),u(t))\lambda(t) + f_u(x(t),u(t))u(t), \quad t \in [0,T],$$

where $f_x$, $f_u$ denote Jacobians of $f$ with respect to the first $n$ variables and the last $m$ variables respectively, and where $\lambda(t) \in \mathbb{R}^n$ and $u(t) \in \mathbb{R}^m$ for all $t$. The original system $\Xi$ is linearly controllable along $(x,u)$ if (2.2) is (completely) controllable in $[0,T]$, i.e. for each $\lambda_1$ and $\lambda_2$ in $\mathbb{R}^n$ there is an essentially bounded $u$ such that, solving (2.2) with this $u$ and with initial condition $\lambda(0) = \lambda_1$ results in $\lambda(T) = \lambda_2$. Linear controllability along a given $(x,u)$ is equivalent to the map $\alpha(u) = \psi(T,\xi,u)$ having full rank at $u$, seen as a map on an appropriate space of controls (see below).

Assume now given both a system $\Xi$ as in (2.1) and an autonomous system $\Omega$, with state space $S_\Omega \subseteq \mathbb{R}^r$ and dynamics denoted by $P$, as well as an analytic map $Q: S_\Omega \to U_\Xi$. We shall use $\Omega \downarrow \Xi$.

---

*By $||f||$ we denote the norm of the Jacobian of $f$ with respect to $u$, for any fixed operator norm.

"Strictly speaking, time-varying systems are not "systems" with our definition."
to denote the system obtained by feeding the output of $\Omega$ as a control to $\Xi$, and think of the corresponding combination as an autonomous system

\[
\begin{align*}
\omega &= P(\omega) \\
\xi &= f(\xi, Q(\omega))
\end{align*}
\]  

(2.3)

with state space $S_\Omega \times S_\Xi$. Consider a pair $(w_0, x_0) \in S_\Omega \times S_\Xi$. For small enough times $T > 0$, the solution $(\omega(t), \xi(t))$ of (2.3) with $\omega(0) = w_0$ and $\xi(0) = x_0$ is defined on the interval $[0, T]$. We shall say that $(w_0, x_0)$ is nondegenerate iff there is some time $T > 0$ such that $\Xi$ is linearly controllable along the ensuing admissible trajectory $(\xi, Q(\omega))$ of $\Xi$, and denote the set of such pairs by $ND(\Omega \downarrow \Xi)$. We also call the trajectory $(\omega, \xi)$ nondegenerate if $(w_0, x_0)$ is. It is easy to see that $ND(\Omega \downarrow \Xi)$ is an open set, and that $(\omega(t), \xi(t))$ is again in $ND(\Omega \downarrow \Xi)$, for each $t \leq T$; see [SO1] for details.

Finally, we say that the system $\Xi$ is complete if for every $\xi \in S_\Xi$, every $T > 0$, and every admissible control $u$, the solution $\psi(t, \xi, u)$ is well-defined for all $t \leq T$, i.e. every control can be applied to every state; it is controllable iff for each $\xi_1$ and $\xi_2$ in $S_\Xi$, $\xi_1$ can be controlled to $\xi_2$. An equilibrium point for $\Xi$ is a pair $(\xi_0, \mu)$, $\xi_0 \in S_\Xi$, $\mu \in U_\Xi$, such that $f(\xi_0, \mu) = 0$.

**Main Theorem.** Assume that the system $\Xi$ is controllable and that, either it has some equilibrium point, or it is complete and $S_\Xi$ is simply connected. Let $C$ be any compact subset of $S_\Xi$. There exists then an autonomous polynomial system $\Omega$, a polynomial map $Q$, and a compact subset $\mathcal{O}$ of $ND(\Omega \downarrow \Xi)$ such that the following property holds:

for each $\xi_1$ and $\xi_2$ in $C$ there are a $T > 0$ and an admissible trajectory $(\omega(t), \xi(t))$ of the system (2.3) with $\xi(0) = \xi_1$ and $\xi(T) = \xi_2$ and such that $(\omega(t), \xi(t)) \in \mathcal{O}$ for all $t \in [0, T]$. ■

Controllability (and (\star)) alone are not sufficient to insure the desired conclusions. A counterexample will be provided later. Note that systems with non-simply connected state space appear naturally in robotics, when there are workspace obstacles.

Assumption (\star) is made mainly for simplicity of exposition, and it can be relaxed considerably. In any case, most types of systems can be modelled in this way. Certainly the usual case of systems linear in controls is included. More general nonlinearities can also be included if there are control bounds. For instance, a system with $f(x, u) = u + u^2$ and $|u| \leq 1$ can be modeled by with $f(x, v) = \sin(v) + \sin^2(v)$, where now $U_\Xi = \mathbb{R}$ and (\star) is satisfied. Similarly open constraint sets can be included: for instance if $u$ above is restricted to the interval $|u| < 1$ then we may reparametrize controls as $u = (2/\pi) \arctan(v)$. In any case, the need for property (\star) is most probably due only to our method of proof; one could rewrite all our treatment using instead "almost uniform" convergence. This would be less elegant than using $p$-convergence as below, but would afford greater generality.

We make the following notational convention in order to save space: to display column vectors, we use also the alternative notation

\[(a_1 : \cdots : a_r)\]  

(2.4)

(note the ":") instead of

\[
\begin{bmatrix}
| a_1 \\
| \cdot \\
| \cdot \\
| a_r
\end{bmatrix}
\]

If the $a_i$ are scalars, this is the same as the transpose of the row vector $(a_1, \cdots, a_r)$, but we will mostly deal with cases in which the $a_i$ are themselves column vectors, in which case (2.4) would correspond to, in more usual but cumbersome notation, $(a_1', \cdots, a_r')$.\]
3. Approximation results.

We need next a number of approximation results. The first subsection deals with continuity properties and differentiability of the input/state map, and the second develops a construction related to standard proofs of the Stone-Weirstrass theorem.

3.1. Continuous dependence theorems.

The results in this section are probably known at the 'folk' level, but we have been unable to find a suitable reference in the form needed for this paper, so we give a self-contained presentation.

A system \( \Xi \) will be fixed for the rest of this section. A real number \( T>0 \) will be also fixed. We let \( L^\infty_\Xi \) be the Banach space of all essentially bounded measurable functions \( [0,T] \to U = \mathbb{R}^m \), endowed with the sup norm
\[
|u|_\infty := \text{ess sup} \{ |u(t)|, t \in [0,T] \}
\]
where \( |u| \) is the Euclidean norm in \( \mathbb{R}^m \) -any other norm could be used instead. (We also use the notation \( |\xi| \) for the Euclidean norm in the state space \( S \subseteq \mathbb{R}^n \).) Since the interval of definition is finite, the spaces \( L^p_\Xi \) \((p\text{-integrable functions})\), \( p \geq 1 \), all contain \( L^\infty_\Xi \). We shall be interested in the latter space viewed as a subspace of each \( L^p_\Xi \); to avoid confusion, we use a different notation. Thus, \( B^m_\Xi \) will denote \( L^\infty_\Xi \) with the norm
\[
|u|_p := \left\{ \int_0^T |u(t)|^{1/p} dt \right\}^p,
\]
for any \( p \geq 1 \). For simplicity in statements, we also let \( B^m_\Xi \) be the same as \( L^\infty_\Xi \) (with the sup norm). It is a standard fact that whenever \( 1 \leq p < q \leq \infty \),
\[
|u|_p \leq c_1 |u|_q
\]
for all \( u \in L^\infty_\Xi \), for some constant \( c_1 \). In fact, \( c_1 = T^{1/(p) - (1/q)} \) will do. Conversely, if \( 1 \leq p < q < \infty \) and if \( k \) is a given constant, then there is another constant \( c_2 \) such that
\[
|u|_q \leq c_2 |u|_p
\]
whenever \( |u|_\infty \leq k \). (Proof: write
\[
|u|^q = |u|^q |u|^p \leq k^q |u|^p
\]
and integrate.) Thus, as long as one remains in a bounded subset of \( L^\infty_\Xi \) all the \( p \)-topologies \((p<\infty)\) are equivalent.

Recall that the continuous mapping \( f: D \to \mathbb{R}^n \), where \( D \) is an open subset of the normed space \( N_1 \), and \( N_2 \) is another normed space, is (Fréchet) differentiable at a point \( \xi \in D \) iff there is a linear mapping \( Df(\xi): N_1 \to N_2 \) such that
\[
||f(x)-f(\xi)-Df(\xi)(x-\xi)|| = o(||x-\xi||).
\]
The derivative of \( f \) is the mapping \( Df: D \to L(N_1,N_2) \) mapping \( \xi \) into \( Df(\xi) \). One defines second derivatives of \( f \) via derivatives of \( Df \), and so on inductively. A smooth \( f \) is one that has derivatives of all orders. We shall say that \( f \) has full rank at \( \xi \) iff \( f \) is a submersion there, i.e. \( Df(\xi) \) is onto. The normed spaces \( B^m_\Xi, p<\infty \), are not Banach -they are dense in the respective \( L^m_\Xi \)- but we shall apply the implicit function theorem to differentiable mappings \( B^m_\Xi \to \mathbb{R}^n \). This will present no difficulty because such a map already
has full rank when restricted to an appropriate finite dimensional subspace, and the implicit function
theorem can be applied to the restricted map.

The following situation will arise below. Assume that
\[ f: S \times U \rightarrow \mathbb{R} \]
is a \( C^2 \) map, and that \( K_1 \subseteq S_2 \) is a given compact convex set such that, for some constant \( k \),
\[ \| f'(\xi, \mu) \| \leq k \tag{3.1} \]
whenever \( \xi \in K_1 \) and \( \mu \in U_2 \). When \( f \) has linear growth in \( u \), as assumed for the map defining the dynamics
of \( \Xi \), this property will hold for all compact sets \( K_1 \). We have the following observation.

**Lemma 3.1:** Assume that \( f, K_1, k \) are as above. Pick a compact subset \( K_2 \subseteq U_2 \). Then, there exist
constants \( M \) and \( N \) such that, if \( \xi, \eta \in K_1 \) and \( \mu, \nu \in K_2 \),
\[ |f(\xi, \mu) - f(\eta, \nu)| \leq M \| \xi - \eta \| + M \| \mu - \nu \| \]
and
\[ |g(\eta, \nu)| \leq N \| \xi - \eta \|^2 + \| \mu - \nu \|^p. \tag{3.2} \]

**Proof:** Property (a) is obtained by separately bounding \( |f(\xi, \mu) - f(\eta, \nu)| \) and \( |f(\eta, \mu) - f(\eta, \nu)| \), and using
property (3.1) and the mean value theorem. We now prove property (b). Assume first that \( \| \mu - \nu \| < 1 \). Then
\( \nu \) is in the compact set \( K_3 := \{ \nu \mid \| \nu - u \| \leq 1 \text{ for some } u \in K_2 \} \).

By Taylor’s formula with remainder (recall that \( f \) is twice differentiable,) we know that, for \( \xi, \eta \) in \( K_1 \) and
\( \mu, \nu \in K_3 \),
\[ |g(\eta, \nu)| \leq a \| \xi - \eta \|^2 + b \| \mu - \nu \|^2 \]
for some constants \( a, b \) (which depend on \( K_1 \) and \( K_3 \), and hence on \( K_2 \)). Since \( \| \mu - \nu \| \leq 1 \) and \( p \leq 2 \), this
means that also
\[ |g(\eta, \nu)| \leq a \| \xi - \eta \|^2 + b \| \mu - \nu \|^p. \tag{3.2} \]

Next note that \( g_{\mu}(x, u) = f_x(x, u) - f_x(\xi, \mu) \), so that \( g \) also satisfies (3.1) (with \( 2k \) instead of \( k \)). We can then
apply part (a) to \( g \) to conclude that, for \( \eta, \mu, \nu \) as in the statement,
\[ |g(\eta, \nu) - g(\eta, \mu)| \leq M' \| \mu - \nu \| \]
for a constant \( M' \) that depends only on \( K_1 \). If \( \| \mu - \nu \| > 1 \), then also \( \| \mu - \nu \|^{p-1} < 1 \), so \( \| \mu - \nu \| < \| \mu - \nu \|^p \). Thus
\[ |g(\eta, \nu)| \leq |g(\eta, \mu)| + |g(\eta, \nu) - g(\eta, \mu)| \leq a \| \xi - \eta \|^2 + M' \| \mu - \nu \|^p. \]

Choosing \( N := \max\{a, b, M'\} \), the result follows. ■

For the given system \( \Xi \), let \( D \) be the set of triples
\[ (t, \xi, u) \in [0, T] \times S_2 \times L_\Xi^m \]
for which the solution \( \psi(t, \xi, u) \) is defined for all \( 0 \leq t \leq T \). It is a standard fact that \( D \) is open, and that \( \psi(t, \cdot, \cdot) \)
is smooth on
\[ D_t := \{ (x, u) \mid (t, x, u) \in D \text{ for all } 0 \leq t \leq T \} \]
for each \( t \). See for instance [GR], theorem 2.9 and proposition 2.11. We shall need differentiability and
continuity with respect to \( p \)-norms, \( p < \infty \), as well.
Lemma 3.2: Pick any \(1 \leq p \leq \infty\), and consider \(D_{\Sigma}\) as a subset of \(S_\Sigma \times B^m_{p}\). Then \(D_{\Sigma}\) is open and the mapping 
\[
\alpha: D_{\Sigma} \to S_\Sigma, \; \alpha(\xi, u) := \psi(T, \xi, u)
\]
is continuous. If \(p > 1\), then \(\alpha\) is also differentiable, and in that case
\[
D\alpha(\xi, u)[\lambda, \upsilon] \text{ is the solution } \lambda(T) \text{ of the variational equation } (2.2), \text{ where } x(t) = \psi(t, \xi, u) \text{ and } \lambda(0) = \lambda_0. \text{ In particular, } \alpha(\xi, \cdot) \text{ has full rank at } u \text{ if and only if } \Sigma \text{ is linearly controllable along } (x, u).

(Thus the full rank property is independent of the particular \(p > 1\).)

Proof: We first assume that \(S_\Sigma = \mathbb{R}^n\) and that the map \(f\) defining the evolution is defined on all of \(\mathbb{R}^n \times \mathbb{R}^m\) and is globally Lipschitz, meaning that there is a constant \(M\) such that
\[
|f(\xi, \mu) - f(\eta, \nu)| \leq M(|\xi - \eta| + |\mu - \nu|)
\]
for all \(\xi, \eta\) in \(\mathbb{R}^n\) and all \(\mu, \nu\) in \(\mathbb{R}^m\). In this case, solutions are always defined, so \(D_{\Sigma} = \mathbb{R}^n \times B^m_{p}\). Assume \(T\) that \((x, u)\) and \((y, v)\) are both admissible trajectories. We have that, for each \(0 \leq t \leq T\),
\[
x(t) - y(t) = \int_0^T (f(x(\tau), u(\tau)) - f(y(\tau), v(\tau))) \, d\tau + x(0) - y(0).
\]
By the Lipschitz condition,
\[
|x(t) - y(t)| \leq M \int_0^T |x(\tau) - y(\tau)| \, d\tau + |x(0) - y(0)| + M|u - v|_p.
\]
By the Bellman-Gronwall lemma, we conclude that
\[
|x(t) - y(t)| \leq e^{MT} \{ |x(0) - y(0)| + M|u - v|_p \}
\]
for all \(0 \leq t \leq T\). Thus, for each \(1 \leq p \leq \infty\) there are constants \(a, b\) such that
\[
|\psi(t, \xi, u) - \psi(t, \eta, v)| \leq a|\xi - \eta| + b|u - v|_p
\]
for all \(\xi, \eta\) in \(\mathbb{R}^n\), all \(u, v\) in \(B^m_{p}\), and all \(0 \leq t \leq T\).

Assume now that \(S_\Sigma\) and \(f\) are arbitrary. Pick any element \((\xi, u)\) in \(D_{\Sigma}\). Choose open neighborhoods \(V_\xi\) and \(W_\xi\) of \(\xi\) such that
\[
V_\xi \subseteq \text{clos}(V_\xi) \subseteq W_\xi \subseteq S_\Sigma.
\]
Let \(\theta: \mathbb{R}^n \to \mathbb{R}\) be any smooth function which is identically 1 on \(\text{clos}(V_\xi)\) and vanishes outside \(W_\xi\). Consider the system obtained with \(S_{\Sigma'} = \mathbb{R}^n\), same \(U_\Sigma\), and \(f\) replaced by
\[
h(\xi, \mu) := \theta(\xi)f(\xi, \mu).
\]
Since \(f\) has linear growth in \(u\), \(h\) also does, and hence since \(\theta\) has compact support we are in the situation of (a) in lemma 3.1. Thus \(h\) is globally Lipschitz. So the arguments in the previous paragraph apply to the system with dynamics \(h(\xi, \mu)\). We let \(\phi\) be the transition map \(\psi\) for this system. By (3.3), there is then a neighborhood \(U_\xi\) of \(\xi\) and an \(\varepsilon > 0\) such that \(\phi(\tau, \eta, v)\) is in \(V_\xi\) for all \(0 \leq \tau \leq T\) whenever \(\eta \in U_\xi\) and \(|u - v|_p < \varepsilon\). Since \(h(\cdot, \mu)\) and \(f(\cdot, \mu)\) coincide on \(V_\xi\), it follows that \(\psi(\tau, \eta, v)\) solves the original differential equation, i.e. it equals \(\phi(\tau, \eta, v)\) for these \(\tau, \eta, v\). In particular, \(D_{\Sigma}\) contains a neighborhood of \((\xi, u)\) and is therefore open. Continuity of \(\alpha\) follows from (3.3).

We now prove differentiability when \(p > 1\). Let \((x, u)\) be an admissible trajectory, and
\[
A(t) = f_x(x(t), u(t)), \quad B(t) = f_u(x(t), u(t)).
\]
Pick a convex compact neighborhood $V_\xi$ of $\xi = x(0)$ and any $\eta$ in $V_\xi$. For any other control $v$ (of length $T$) sufficiently near to $u$ in $B_1^p$, let $(z,v)$ be the trajectory that results when applying $v$ to $\eta$. By continuity, we may choose a suitable neighborhood of $u$ so that this trajectory stays always in a given compact convex neighborhood of $\xi$ in $S$, say $K$. Let $K$ be any compact set such that the (essentially bounded) control $u$ satisfies $u(t) \in K$ for almost all $t$. Let $\delta(t) := z(t) - x(t)$ and $\upsilon(t) := v(t) - u(t)$. From part (b) of lemma 3.1 it follows that, if $1 \leq p \leq 2$ then

$$\delta(t) = A(t)\delta(t) + B(t)\upsilon(t) + \phi(t)$$

where

$$|\phi(t)| \leq N(|\delta(t)|^2 + |u(t)|^p)$$

for a suitable constant $N$. Thus, if $\lambda$ solves (2.2) with $\lambda(0) = \delta(0) = \xi - \eta$, it follows that

$$\delta(T) = \lambda(T) + \int_0^T \Phi(T,\tau)\phi(\tau)d\tau.$$ 

So

$$|\delta(T) - \lambda(T)| \leq M\int_0^T |\delta(t)|^2dt + \|u\|_p^p$$

for some constant $M$. Applying (3.3) to the first term there results that there is a constant $M'$ such that

$$|\delta(T) - \lambda(T)| \leq M'|\lambda(0)|^2 + \|u\|_p^2.$$

(3.4)

Since $p > 1$, it follows that $|\delta(T) - \lambda(T)|$ is majorized by an expression

$$M'|\lambda(0)|^2 + \|u\|_p^2,$$

again as desired. \(\blacksquare\)

**Remark 3.3:** The differentiability result is false if $p=1$. For instance, consider the system

$$x = \sin^2 u$$

with $S = U = \mathbb{R}$, and the controls $u_\varepsilon$ on $[0,1]$ with

$$u_\varepsilon(t) = 1 \text{ on } [0,\varepsilon] \text{ and } u_\varepsilon(t) = 0 \text{ for } t > \varepsilon.$$ 

Let also $u = 0$, $x = 0$, and $x_\varepsilon := \text{solution when applying } u_\varepsilon \text{ to } 0$. Note that $u_\varepsilon \to u$ when $\varepsilon \to 0$. The differential of $u(\cdot) \to \psi(T,0,u)$ as a map on $B_1^1$, if it exists, would have to be the mapping which is identically zero. Thus differentiability would mean that $|x_\varepsilon(T)| = o(\|u_\varepsilon\|_1)$ as $\varepsilon \to 0$. Since $|x_\varepsilon(T)| = \varepsilon = \|u_\varepsilon\|_1$, this is false. (Note that, on the other hand, for $p > 1$ one has for this example that

$$\|u_\varepsilon\|_p = \varepsilon^{1/p},$$

and there is no contradiction.) \(\blacksquare\)

**Remark 3.4:** For $p < \infty$ the linear growth condition is essential. Otherwise not even continuity holds. Indeed, take any finite $p$ and consider the equation $x = u^q$, where $q > p$ is arbitrary. Pick any $r$ with $q > (1/r) > p$. The control $u_\varepsilon$ defined now by

$$u_\varepsilon(t) := \varepsilon^r \text{ for } t \leq \varepsilon$$

and zero otherwise, has $\|u_\varepsilon\|_p \to 0$ as $\varepsilon \to 0$, but the corresponding solution $x_\varepsilon$ has
3.2. Approximation of PC controls by polynomial controls.

We fix a $T>0$ and an integer $\sigma$. For any elements $v_0, \ldots, v_\sigma$ in $U_2$, and for any real numbers $0=s_0<s_1<\cdots<s_\sigma<s_{\sigma+1}=T$, consider the piecewise constant admissible control on $[0,T]$ defined as follows:

$$u(s_1, \ldots, s_\sigma; v_0, \ldots, v_\sigma; t) := v_i \text{ if } s_i \leq t < s_{i+1}, \quad i=0, \ldots, \sigma.$$ 

Let $\{Q_n(t)\}$ be any fixed sequence of polynomial kernels of degree $2n$, that is, each $Q_n$ is a polynomial of degree $2n$ and the following properties hold:

1. For each $\delta>0$, $Q_n \to 0$ as $n \to \infty$, uniformly on $|t| > \delta$, $t \in [-T, T]$.
2. $\int_{-T}^T Q_n(t) \, dt = 1$ for all $n$, and
3. $Q_n(t) \geq 0$ for all $t \in \mathbb{R}$ and all $n$.

For instance, we may take

$$Q_n(t) := k_n (T-t)^n,$$

where the $k_n$ are appropriately chosen constants. Consider now the convolution:

$$p_n(s_1, \ldots, s_\sigma; v_0, \ldots, v_\sigma; t) := \int_{-T}^T Q_n(t-\tau) u(s_1, \ldots, s_\sigma; v_0, \ldots, v_\sigma; \tau) \, d\tau$$

as a function on $t \in [0,T]$ with values in $\mathbb{R}^m$. (Integration of vector functions is understood componentwise.) If we expand

$$Q_n(t-s) = q(t-s),$$

then $p_n(t)$ equals

$$\sum_{i=0}^{2n} q_i(t) s_i.$$ 

Thus, $p_n$ is a (vector) polynomial in $(s_1, \ldots, s_\sigma; v_0, \ldots, v_\sigma; t)$ of degree $2n$.

The expression in the right-hand side of (3.8) can be rewritten as

$$\int_{-T}^T Q_n(t) u(s_1, \ldots, s_\sigma; v_0, \ldots, v_\sigma; t) \, dt,$$

if we identify $u$ with its extension to $(-\infty, \infty)$ obtained by setting $u \equiv 0$ outside $[0,T]$. Let $|\cdot|$ denote the Euclidean norm in $\mathbb{R}^m$, and fix any $p \geq 1$. Note that

$$\|p_n(s_1, \ldots, s_\sigma; v_0, \ldots, v_\sigma; t) - u(s_1, \ldots, s_\sigma; v_0, \ldots, v_\sigma; t)\|_p^p = \int_0^T \|p_n(s_1, \ldots, s_\sigma; v_0, \ldots, v_\sigma; t) - u(s_1, \ldots, s_\sigma; v_0, \ldots, v_\sigma; t)\|_p^p \, dt.$$ 

By property (3.6), we may write

$$u(s_1, \ldots, s_\sigma; v_0, \ldots, v_\sigma; t) = \int_{-T}^T Q_n(s) u(s_1, \ldots, s_\sigma; v_0, \ldots, v_\sigma; t) \, ds,$$

so the expression in (3.10) is bounded above by

$$\int_0^T \left| \int_{-T}^T Q_n(t)(u(s_1, \ldots, s_\sigma; v_0, \ldots, v_\sigma; t-\tau) - u(s_1, \ldots, s_\sigma; v_0, \ldots, v_\sigma; t)) \, d\tau \right|_p^p \, dt.$$ 

Assume a given sequence $(s_1, \ldots, s_\sigma)$ as above, a real number $\delta$...
with $T\delta > 0$, 
and a $t \in [0, T]$ which does not belong to any of the intervals 
$[s_i - \delta, s_i + \delta]$, for any $i = 0, 1, \ldots, \sigma + 1$. (Where $s_0 := 0$ and $s_{\sigma + 1} := T$.)
For any $\tau$ such that $|\tau| < \delta$, it follows that $u(s_1, \ldots, s_\sigma; \nu_0, \ldots, \nu_\sigma; t-\tau) = u(s_1, \ldots, s_\sigma; \nu_0, \ldots, \nu_\sigma; t)$, 
and hence the inside integral in (3.11) can be replaced by the 
integral over $|\tau| > \delta$. (As long as $t$ is of this type.) Since the 
differences 

$$|u(s_1, \ldots, s_\sigma; \nu_0, \ldots, \nu_\sigma; t-s) - u(s_1, \ldots, s_\sigma; \nu_0, \ldots, \nu_\sigma; t)|$$

are always bounded by 
$c_1 := 2\max(|\nu_j|)$, it follows that for such $t$ the term inside the integral 
is bounded by 

$$\{c_1 \int_{J_{\delta}} Q_\eta(\tau)d\tau\}^p,$$

where $J_{\delta}$ is 
$[-T, -\delta] \cup [\delta, T]$. 
When $t$ is not in any of the above intervals, the 
inside term is in any case bounded by $\{c_1\}^p$, and the set of such 
exceptional $t$ has measure at most $(\sigma + 2)\delta$. We conclude that the 
expression in (3.11) is majorized by 

$$(\sigma + 2)\delta (c_1)^p + \{c_1 \int_{J_{\delta}} Q_\eta(\tau)d\tau\}^p.$$ 

By property (3.5), the following result holds:

**Lemma 3.5:** For any $1 \leq p < \infty$, $p_n(s_1, \ldots, s_\sigma; \nu_0, \ldots, \nu_\sigma)$ converges in $B_p^m$ to $u(s_1, \ldots, s_\sigma; \nu_0, \ldots, \nu_\sigma)$. This 
convergence is uniform on the real numbers $0 < s_1 < \ldots < s_\sigma < T$, and is also uniform on the vectors $\nu_0, \ldots, \nu_\sigma$ 
on compact subsets of $U_{s_\sigma + 1}$. 

The result is of course false for $p = \infty$, since a limit of polynomials 
in $L^\infty$ is necessarily continuous. For this reason we have introduced 
the spaces $B_p^m$, $p = \infty$. An alternative approach would be based on the 
notion of "almost uniform" convergence, for which a similar result can be proved.
4. Several controllability notions.

We next introduce various very natural strong notions of controllability, and eventually prove that they are all in fact equivalent.

4.1. Nonsingular controllability.

Let a system $\Xi$ and a $T>0$ be fixed. We shall say that a control $u$ on $[0,T]$ nonsingularly (or, ns-) steers $\xi$ into $\zeta$ iff $u$ can be applied to $\xi$ and the resulting trajectory $(x,u)$ is such that $x(T)=\zeta$ and $\Xi$ is linearly controllable along $(x,u)$. We also say that $u$ can be "nonsingularly applied" to $\xi$. If such an $u$ exists, $\xi$ can be ns-controlled into $\zeta$. If every $\xi$ can be nonsingularly controlled to every other $\zeta$, the system $\Xi$ is ns-controllable.

The notion of ns-controllability is transitive in the following strong sense. Assume that $\xi$ can be ns-controlled to $\eta$ and that $\eta$ can be controlled to $\zeta$ (not necessarily nonsingularly). Then it is also true that $\xi$ can be ns-controlled to $\zeta$. This is because if $w$ is the concatenation of a control $u$ (of length $T$) which ns-steers $\xi$ into $\eta$ with a control $v$ (of length $S$) which steers $\eta$ into $\zeta$, then $w$ is a control (of length $T+S$) which ns-steers $\xi$ into $\zeta$. (The differential of $\psi(T+S,\xi,\cdot)$ is full rank already at those variations $\nu$ which are zero on $[T,T+S]$.)

A particular type of nonsingularity is as follows. Assume that the control $u$ is piecewise constant, $u = u(s_1,\ldots,s_\sigma;v_0,\ldots,v_\sigma;\cdot)$, of length $T$ and it steers the state $\xi$ into $\zeta$. We shall say that $u$ pcns- (piecewise constant nonsingularly) steers $\xi$ to $\zeta$ if the mapping

$$(v_0,\ldots,v_\sigma) \mapsto \psi(T,\xi,u(s_1,\ldots,s_\sigma;v_0,\ldots,v_\sigma;\cdot)), \tag{4.1}$$

defined on a neighborhood of $(v_0,\ldots,v_\sigma)$, has differential of full rank at $(v_0,\ldots,v_\sigma)$. In that case, $u$ also ns-steers $\xi$ into $\zeta$. This is because the mapping in (4.1) is the composition of the linear bounded map

$$(v_0,\ldots,v_\sigma) \mapsto \psi(T,\xi,u(s_1,\ldots,s_\sigma;v_0,\ldots,v_\sigma;\cdot)) \tag{4.2}$$

with $\psi(T,\xi,\cdot)$, hence the latter must have full rank at $u$.

As above, we define $\xi$ to be pcns-controllable to $\zeta$ if such an $u$ exists, and the system $\Xi$ is pcns-controllable if this happens for any pair of states. This notion is also transitive in the sense discussed above.

4.2. Strong normal controllability.

We shall say that the control $u$ of length $T$ strongly normally (or, sn-) steers the state $\xi$ to the state $\zeta$ in time $T$ iff there exist an integer $\sigma$, elements $v_0,\ldots,v_\sigma$ in $U_\zeta$, a neighborhood $V_\zeta$ of $\zeta$, and a smooth mapping

$\beta: V_\zeta \rightarrow \mathbb{R}^\sigma$

such that, for each $z \in V_\zeta$, if $\beta(z) = (s_1,\ldots,s_\sigma)$ then $0<s_1<\cdots<s_\sigma<T$, the control $u(\beta(z);v_0,\ldots,v_\sigma;\cdot)$ (of length $T$)
steers \( \xi \) into \( z \) in time \( T \), and \( u(\beta(\xi);\nu_0,\ldots,\nu_d) = u \).

The state \( \xi \) can be sn-controlled to \( \zeta \) (in time \( T \)) if such an \( u \) exists. The system \( \Xi \) is sn-controllable if for each \( \xi, \zeta \) in \( S_\Xi \) there is a \( T > 0 \) such that \( \xi \) can be sn-controlled to \( \zeta \) in time \( T \).

This notion is closely related to that of normal controllability given in [SU1]; the qualifier "strong" refers to the fact that the controls \( u \) are required to (locally) all have a uniform length \( T \).

As with the other definitions, if \( \xi \) is sn-controllable into \( \eta \) and \( \eta \) is controllable into \( \zeta \), then \( \xi \) is sn-controllable into \( \zeta \).

**Remark 4.1:** For particular states and controls, sn- and ns-controllability are (for systems not linear in controls) different. For example, consider the system (with \( U_\Xi = S_\Xi = \mathbb{R} \))

\[
\dot{x} = x + 1 - \sin(u)
\]

and \( \xi = 0, \zeta = 2(e^{1/2} - 1), T = 1, \nu_0 = \pi/2, \nu_1 = -\pi/2, \nu = 1/2, \) and

\[
\beta(z) := 1 + \ln 2 - \ln(2 + z)
\]

for \( z \) near \( \zeta \). Then

\[
u = \begin{cases} 
\pi/2 & \text{if } 0 \leq s < 1/2 \\
-\pi/2 & \text{if } 1/2 \leq s \leq 1
\end{cases}
\]

sn-controls \( \xi \) to \( \zeta \). But it does not do so nonsingularly, since along the corresponding trajectory the linearization is the autonomous system

\[
\dot{x} = x
\]

The corresponding notions for systems (rather than individual controls) do coincide (proved below). The situation is closely related to that in the context of orbit theorems for nonlinear continuous time systems (see [SO2]), where different topologies are induced for the same state space depending on whether one takes the finest topology that makes all motions continuous with respect to switching times or instead with respect to control values.

**Remark 4.2:** Controllability is by itself not equivalent to sn-controllability. For instance consider the system with \( U_\Xi = \mathbb{R}, S_\Xi = \mathbb{R}^2 - \{(0,0)\} \), and equations in polar coordinates:

\[
\theta = 1
\]
\[
r = ru
\]

The system is controllable (any state can be steered to every other state in time \( 2\pi \)). But the set of states reached in time precisely \( T \) is a half-line, and hence has no interior. Note that the state space is not simply connected, and that there are no equilibrium points. The “clock” coordinate \( \theta \) is responsible for the pathological behavior of this example.

Let \( L \) be the Lie algebra associated to \( \Xi \). This is the smallest Lie algebra of vector fields on \( S_\Xi \) which contains the vector fields

\[
\{f(\cdot, \mu), \mu \in U_\Xi \}
\]

For any \( \xi \in S_\Xi \), we associate the following subset of the tangent space at \( \xi \):
\( L(\xi) := \{X(\xi), X \in L\} \).

If \( \xi \) is controllable, then it is a well-known fact that \( L \) has full rank (i.e. \( \dim L(\xi) = n \)) at all \( \xi \). (See [IS] for many basic results on the Lie algebraic aspects of control systems.) The ideal of \( L \) generated by all the differences

\[
\{f(\cdot,\mu) - f(\cdot,\nu), \ \mu, \nu \in U_\xi\}
\]

is the zero-time algebra \( L^0 \). Similarly, we introduce the spaces \( L^0(\xi) \) as above. It follows from the definitions that, for any fixed \( \mu \in U_\xi \),

\[
L(\xi) = L^0(\xi) + \text{span}\{f(\xi,\mu)\}
\]

for all \( \xi \in S_\xi \). It is also known that (because of controllability), \( L^0 \) has constant rank, so that there are only two possibilities:

- either \( \dim L^0(\xi) \) is always \( n \) or it is always \( n-1 \). In the latter case, a local change of coordinates always can be found which results in dynamics with an autonomous coordinate

\[
\dot{x}_1(t) = f_1(x_1).
\]

Thus there is (locally) a "clock" as in remark 4.2. When there is an equilibrium point \( f(\xi,\mu) = 0 \), equation (4.3) together with the constancy of rank, gives that \( L^0(\xi) \) has full rank, meaning that \( L^0(\xi) \) has rank \( n \) at every point. When instead \( S_\xi \) is simply connected and the system is complete, this also true by a result of Elliot (see [E], [SJ]). We summarize then:

**Proposition 4.3:** If the system \( \xi \) is as in the statement of the main Theorem, then \( L^0 \) has full rank. ■

We shall prove that the full rank of \( L^0 \) is sufficient for the conclusions of the theorem to hold. This rank condition is also necessary, because the conclusions imply that the system is ns-controllable, and this will be shown below to be equivalent to the rank condition.

If \( T > 0 \), \( \xi \in S_\xi \), and \( 0 < s_1 < \cdots < s_\sigma < T \), we let

\[
A^T_{s_1,\ldots,s_\sigma}(\xi) = \{\psi(T,\xi,\mu(s_1,\cdots,s_\sigma,v_0,\cdots,v_\sigma^{-1})) \mid v_0,\cdots,v_\sigma \in U_\xi\}.
\]

Note that, by the implicit function theorem, if \( \xi \) can be pcnns-controlled to some other state \( \zeta \), then some set as in (4.4) has a nonempty interior. We remark below that the converse is also true.

Let \( A_{\text{PC}}(\xi) \) denote the union of all sets as in (4.4), for all possible \( T > 0 \), i.e. the set of states reachable from \( \xi \) using piecewise constant controls.

Controllability using arbitrary controls is equivalent to controllability using just piecewise constant controls. The next lemma is well-known; see for instance [SU2], theorem 1.
Lemma 4.4: If $\Xi$ is controllable, then $A_{PC}(\xi) = S_\Xi$ for all $\bar{\xi}$.■

4.3. A fixed-point argument.
We shall need an argument based in the Brouwer fixed point theorem that has been used repeatedly in control theory ("Brunovsky-Lobry lemma"), and which is also used in the main step of the proof of the preservation of controllability under sampling (see e.g., [SO3]). An abstract version is provided by [GR], lemma 3.2, (see also [LM], pp. 251-252,) which we reproduce here in somewhat weaker form. Choose any $n$ norm in $\mathbb{R}^n$.

Lemma 4.5: Let $W$ be a topological space and let $H: W \to \mathbb{R}^n$ be continuous. Assume that for some $\zeta$ in $\mathbb{R}^n$ there is a neighborhood $V$ of $\zeta$ and a continuous map $\beta: V \to W$ such that $H(\beta(z)) = z$ for all $z$ in $V$. Then, there are an $\epsilon > 0$ and an open neighborhood $V'$ of $\zeta$ such that, for any $\varepsilon > 0$ and an open neighborhood $V'$ of $\zeta$ such that, for any mapping

$$h: W \to \mathbb{R}^n$$

with $|h(x) - H(x)| < \epsilon$ for all $x$, necessarily $V' \subseteq h(W)$.■

Let $P_{k,T}(\xi)$ denote the set of states that can be reached from $\xi$ using polynomial controls of length $T$ and degree at most $k$ in $t$.

Lemma 4.6: If $\xi$ can be sn-controlled to $\zeta$ in time $T$, then there exists a $k$ such that $\zeta$ is in the interior of $P_{k,T}(\xi)$.

Proof: Assume that $\bar{\xi}$, $\bar{\zeta}$, $u$, $T$, $v_0, \ldots, v_\alpha$, $\beta$, $V_{\zeta}$ are as in the definition of sn-steering. Restricting $V_{\zeta}$ if necessary, we will assume that it is compact. Let $W := \beta(V_{\zeta})$, a compact subset of $\mathbb{R}^\alpha$ which contains $\beta(\zeta) = s^0 = (s_0^0, \ldots, s_0^\alpha)$. Let

$$H: W \to \mathbb{R}^n, (s_1, \ldots, s_\alpha) \to \psi(T, \bar{\zeta}, u(s_1, \ldots, s_\alpha, v_0, \ldots, v_\alpha)).$$

Thus we are in the situation of lemma 4.5, with $V = V_{\zeta}$; let $\epsilon$, $V'$ be as in the conclusions there. We now construct a sequence of mappings $\{H_N\}$ from $W$ into $\mathbb{R}^n$ which converges uniformly to $H$, and with the property that the image of each $H_N$ is included in the set of all states reachable from $\xi$ using polynomial controls of degree at most $2N$. So for $n$ large enough one of these images contains $V'$, and the lemma follows.

Consider, for the above $v_0, \ldots, v_\alpha$, the mapping

$$(s_1, \ldots, s_\alpha) \to u(s_1, \ldots, s_\alpha, v_0, \ldots, v_\alpha)$$

seen as a map from $W$ into (for instance) $B_{2n}$. This is continuous (but is not differentiable). Let $K$ be the image of $W$ under this mapping. Thus $K$ is a compact subset of the open subset of $B_{2n}$ consisting of all the controls (of length $T$) that can be applied to $\bar{\xi}$. Thus there exists a $\delta > 0$ such that every admissible control $p$ which is at distance less than $\delta$ from $K$ can also be applied to $\bar{\xi}$. For each positive integer $N \geq 1$, let

$$H_N(s_1, \ldots, s_\alpha) := \psi(T, \bar{\zeta}, p_N(s_1, \ldots, s_\alpha, v_0, \ldots, v_\alpha)),\]
where the polynomials $p_N$ are as in section 3.2. Since the $p_N$ converge to $u$ uniformly on the $s_i$'s, for $N$ large enough they can be applied to $\xi$. We take the subsequence of the $H_N$ that consists of such large $N$. Since $\psi$ is continuous on $B^m_2$, we conclude that the $H_N$ indeed converge uniformly to $H$. 

**Lemma 4.7:** If for some $k, T$ the interior of $P_{k, T}(\xi)$ is nonempty, then there exist $s_1, \ldots, s_o$ such that $A^T_{s_1, \ldots, s_o}(\xi)$ has a nonempty interior.

**Proof:** This is again proved as a corollary of lemma 4.5, as follows. Let $H(a_0, \ldots, a_k)$ be the state reached when applying to $\xi$ the control (of length $T$)

$$\sum_{i=0}^k a_i t^i.$$ 

(4.5)

This is defined and continuous on an open subset of $\mathbb{R}^{mk}$ (the control must be applicable to $\xi$). It is also smooth, since we may see $H$ as the composition of the (linear, bounded) mapping that sends $(a_0, \ldots, a_k)$ into the element (4.5) of $L^m_\infty$ followed by the mapping $\psi(T, \xi, \cdot)$. The image of the smooth map $H$ contains by assumption an open set. Since the domain of $H$ is a finite-dimensional separable manifold, we may apply Sard's theorem to conclude that its differential is full rank at some point. Applying the implicit function theorem, and restricting the domain of $H$ appropriately, we are again in the situation of the lemma 4.5.

Now we approximate $H$ by mappings $H_N$ constructed as follows. For each $N$ and each $(a_0, \ldots, a_k)$, consider the piecewise constant (sampled) control in $L^m_\infty$ which has in the interval $[kT/N, (k+1)T/N]$ the value of (4.5) at (say) $kT/N$. These converge uniformly to (4.5), and hence are admissible and can be applied to $\xi$ for $N$ sufficiently large. Then $H_N(a_0, \ldots, a_k)$ is by definition the application of this control to $\xi$. Thus $H_N$ contains an open neighborhood of $\zeta$ for large enough $N$, and this proves the lemma (with $\sigma = N-1$).

**4.4. All notions are equivalent.**

The following shows that the controllability notions introduced in this section are very natural. The set of all states to which $\xi$ can be steered in time exactly $T$ is $A(T)(\xi)$.

**Proposition 4.8:** Assume that the system $\Xi$ is controllable. Then the following properties are all equivalent.

1. $L^0$ has full rank.
2. There exist $\xi, \zeta$ in $S_\Xi$ such that $\xi$ can be sn-controlled to $\zeta$.
3. $\Xi$ is sn-controllable.
4. There exist $\xi, \zeta$ in $S_\Xi$ such that $\xi$ can be ns-controlled to $\zeta$.
5. $\Xi$ is ns-controllable.
6. There exist $\xi, \zeta$ in $S_\Xi$ such that $\xi$ can be pcns-controlled to $\zeta$.
7. $\Xi$ is pcns-controllable.
8. Some set as in (4.4) has nonempty interior.
9. Some set $A^T(\xi)$ has nonempty interior.
10. Some set $P_{k,T}$ has nonempty interior.

**Proof:** We pointed out above that (7) implies (5). That (2) implies (10) is proved in lemma (4.6), while lemma (4.7) shows that (10) implies (8).

The "transitivity" properties discussed earlier establish that (2) is equivalent to (3), (4) is equivalent to (5), and (6) is equivalent to (7). Note also that (8) trivially implies (9).

The equivalence between (9) and (1) was proved in [SJ]; see for instance [SO2] for a somewhat more general result.

If (1) holds, then lemma 4.4 together with ([SO3], lemma 2.2), implies that (2) holds.

The implicit function theorem, applied to the map $\psi(T,\xi,\cdot)$ on $L^m$, gives that (4) implies (9).

Finally, statements (6) and (8) are equivalent. Indeed, we already remarked that pcns-controllability implies that some set as in (4.4) has nonempty interior. Conversely, assume that a given such set has nonempty interior. The map (4.1) is smooth (composition of the linear bounded map in (4.2) with $\psi(T,\xi,\cdot)$) and its image is $A^T_{a_1,\ldots,a_\sigma}(\xi)$. Since the domain is a separable finite-dimensional manifold (open subset of $U_\sigma^{\sigma+1}$), we may apply Sard's theorem to conclude that (4.1) must be full rank at some point, i.e. $\xi$ can be pcns-controlled to some $\zeta$.
5. Proof of the Main Theorem.

In this section we prove that the conclusions of the theorem follow from ns-controllability of the system. By the remarks in the previous section, this will be all that is needed in order to prove the theorem. The following is the main technical step needed. It establishes basically that if the system is ns- (or pcns-, or sn-) controllable, then one can transfer states nonsingularly using polynomial controls. We know from lemma 4.8, part (10), that we can do so using polynomial controls. An application of Sard’s theorem will then insure that from each state we can go nonsingularly and polynomially into some other state. But in order to transfer to a predetermined state it is necessary to concatenate this resulting control with another control, and the concatenation will in general not be polynomial but at best a spline. So a different argument, again based on the above fixed-point theorem, is needed.

Proposition 5.1: Assume that $\xi$ and $\zeta$ are in $S_\Xi$ and that $\xi$ is pcns-controllable into $\zeta$ in time $T$. There exist then an integer $\rho$, a compact subset $K$ of $U_\Xi^{\rho+1}$, and neighborhoods $W_\xi$ and $W_\zeta$ of $\xi$ and $\zeta$ respectively, with the following properties:

1. Let $u$ be the control $\nu^t$ of length $T$, where $(\nu, \ldots, \nu)$ is in $K$. Pick any $x \in W_\xi$. Then $u \circ \rho \circ \rho \xi$ can be applied to $x$, and $\xi$ is linearly controllable along the ensuing trajectory.

2. If $x \in W_\xi$ and $z \in W_\zeta$ then there exists some $u$ as above such that $u$ steers $x$ into $z$.

Proof: Let $\xi$, $\zeta$, $u$, $T$, $s_1, \ldots, s_\alpha$, $v_0, \ldots, v_\alpha$ be as in the definition of pcns-steering. Let

$$H(v_0, \ldots, v_\alpha) := \psi(T, \xi, u(s_1, \ldots, s_\alpha, v_0, \ldots, v_\alpha)),$$

defined on a neighborhood of $v_0, \ldots, v_\alpha$. Note that $u$ ns-steers $\xi$ into $\zeta$, as discussed earlier. There is by the implicit function theorem applied to $H$ a neighborhood $V_\zeta$ of $\zeta$ and a smooth $\beta: \zeta \rightarrow \mathbb{R}^{(\alpha+1)m}$

with $H(\beta(z)) = z$ on $V_\zeta$. By continuous differentiability of $\psi(T, \cdot)$ there is a neighborhood $A$ of $u$ (say, in $B_\Xi^n$) and a neighborhood $V_\zeta$ of $\zeta$, such that each $v \in A$ can be applied nonsingularly to each $x$ in $V_\zeta$. Let $W$ be a compact neighborhood of $(v_0, \ldots, v_\alpha)$ such that $u(s_1, \ldots, s_\alpha, v_0, \ldots, v_\alpha)$ is in $A$ whenever $(v_0, \ldots, v_\alpha)$ is in $W$. Consider $H$ as a map restricted to $W$, and restrict $V = V_\zeta$ so that $\beta$ maps into $W$. We apply lemma 4.5 to obtain an $\varepsilon$, $V$ as there. Let $W_\zeta := V$. For each $x \in V_\zeta$ and all large $N$,

$$H_{x,N}(v_0, \ldots, v_\alpha) := \psi(T, x, p_N(s_1, \ldots, s_\alpha, v_0, \ldots, v_\alpha)),$$

(notations as in section 3.2) is well-defined on $W$, and $p_N(s_1, \ldots, s_\alpha, v_0, \ldots, v_\alpha)$ can be nonsingularly applied to $x$. The $H_{x,N}$ converge uniformly to $H$ as $x \rightarrow \zeta$ and $N \rightarrow \infty$. Thus there are a neighborhood $W_\zeta$ of $\zeta$ and an $N$ large enough that

$$W_\zeta \subseteq H_{x,N}(W)$$

and

$$p_N(s_1, \ldots, s_\alpha, v_0, \ldots, v_\alpha)$$

can be nonsingularly applied to $x$. 

(5.1)
for all \( x \in W \) and all \( (\nu, \cdots, \nu) \) in \( W \). By (5.1), if \( x \in W \) and \( z \in W \) then \( z \) is in the image of \( H \). Finally, let 
\[
K := \{(\mu, \cdots, \mu) \mid \text{for some } (\nu, \cdots, \nu) \in W, p_N(s_1, \cdots, s_\sigma, s_1^\cdots s_\sigma t) = \sum_{i=1}^{2N} \mu_i t^{2N-i}\}.
\]
This set is compact, because the coefficients of \( p_N \) are continuous functions of the \( \nu \) (see formula (3.9)).

We may now complete the proof of the theorem. Assume then that the system \( \Sigma \) is \( s\)-controllable, and apply the above proposition to it.

Fix \( \xi, \zeta \), and corresponding \( \rho, K, W_\xi \), and \( W_\zeta \). Choose also an open neighborhood \( V_\xi \) of \( \xi \) with the property that its closure \( \text{clos}(V_\xi) \) is contained in \( W_\xi \). Similarly, pick an open neighborhood \( V_\zeta \) of \( \zeta \) with \( \text{clos}(V_\zeta) \subseteq W_\zeta \). Consider the mapping 
\[
\alpha: \mathbb{R}^{(p+1)m} \to (L_\infty^m)^{p+1},
\]
\[
\alpha(u_0 : \cdots : u_p) := (u_0 : u_0 t + u_1 : \cdots : u_0 t^p + \cdots + u_p).
\]
This is (linear and) continuous. Let \( \chi \) be the last component of this map, 
\[
\chi(u_0 : \cdots : u_p) := (u_0 t^p + \cdots + u_p).
\]
Then, \( \alpha(K) \) is a compact subset \( K' \) of \( (L_\infty^m)^{p+1} \), and \( K' := \chi(K) \) is also compact. By the conclusions of proposition 5.1, each control function \( \omega \in K' \) is admissible for the system \( \Sigma \) and can be applied to each \( x \in W_\xi \). Thus 
\[
[0,T] \times \text{clos}(V_\xi) \times K'
\]
is a compact subset of the domain of \( \psi \). Consider now the mapping
\[
(t,x,w) \mapsto (\alpha(w)(t), \psi(t,x,\chi(w)))
\]
defined on this compact set. This is the composition of the continuous map
\[
(t,x,w) \mapsto (t, \alpha(w), \psi(\cdot, x, \chi(w)))
\]
into \([0,T] \times K \times C[[0,T],[\mathbb{R}^m]]\) with the continuous evaluation mapping
\[
(t,\phi,\tilde{\xi}) \mapsto (\phi(t), \tilde{\xi}(t))
\]
(defined for \( \phi \) on the subspace of continuous functions in \( L_\infty^m \)).
Thus its image \( O_{\Sigma_\xi} \) consisting of all those \( (v,y) \in \mathbb{R}^{(p+1)m} \times S_{\Sigma} \) such that
\[
\exists t \in [0,T], x \in \text{clos}(V_\xi), w \in K^p + 1 \text{ with } v = \alpha(w)(t) \text{ and } y = \psi(t,x,\chi(w))
\]
is also compact.

Let \( \mathbf{C} \) be the compact set in the statement of the theorem. Now cover \( \mathbf{C} \times \mathbf{C} \) by sets of the type \( V_\xi \times V_\zeta \). Let \( V_i \times V'_i \), 
\( i = 1, \ldots, s \) be a finite subcover, and let subscripts \( "i" \) be used for the associated data as above. Write \( O_i \) instead of \( O_{\Sigma_\xi, \xi_i} \), and let \( \rho \) be the largest of the \( \rho_i \), \( T \) the largest of the \( T_i \).

Introduce
\[
\Omega := (\mathbb{R}^m)^\rho \times U_\Sigma = \mathbb{R}^{m(p+1)}.
\]
Finally, let
\[ P(w_0,\cdots:w_p) := (0:w_0,\cdots:w_{p-1}) , \]
\[ Q(w_0,\cdots:w_p) := w_p . \]

These are the maps defining the open-loop control generator. For each
\( i = 1,\cdots,s \), let
\[ O'_i := \{(0,\cdots:0:v:x)\in \Omega \times S \mid (v:x)\in O_i \} , \]
where there are \( \rho - \rho_i \) blocks of zeroes. Each of these is a compact set, so
that their union
\[ O := \cup \{O_i, i = 1,\cdots,s\} \]
also is.

We now prove that this set \( O \) indeed satisfies the properties in the
conclusions of the theorem. We first show that \( O \) is included in \( ND(\Omega\downarrow \Xi) \). For
this it is sufficient to show that each \( O'_i \subseteq ND(\Omega\downarrow \Xi) \). Fix then \( i \), and drop for
the rest of this paragraph the indexes \( i \) - all data will refer to this \( i \).
The elements of \( O' \) are of the form \( (0,\cdots:v:y) \) with \( v = \alpha(w)(t) \) and \( y = \psi(t,x,\chi(w)) \),
for
\[ t \in [0,T], w \in K^{p+1}, x \in \text{clos}(V_\xi) (\xi = \xi_\rho) . \]

This is the same as the solution \( (\omega(t),\xi(t)) \) at time \( t \) of
\[ \omega_0(t) = 0 \]
\[ \omega_p(t) = \omega_{p-1} \]
\[ \xi(t) = f(\xi(t),\omega_p(t)) \]
that starts at \( \omega(0) = w \) and \( \xi(0) = x \). As remarked earlier, \( ND(\Omega\downarrow \Xi) \) is
forward-invariant. Thus it is sufficient to establish that \( (w,x) \) is
in \( ND(\Omega\downarrow \Xi) \). But \( x \in W_\xi \), and \( w = (u_0,\cdots:u_p) \) has all block components
\( u_i \) in \( K \). Thus \( (w,x) \) is indeed nondegenerate, by the conclusions of
proposition 5.1.

Finally, take any \( (x,z) \in C \). Then there is some \( i \) such that \( (x,z) \) is
in \( V_\chi \times V_\psi^{\prime} \), and hence is in \( W_\chi \times W_\psi^{\prime} \). Thus there is a sequence
\( w \) in \( K \) such that \( \chi(w) \) (ns-\) steers \( x \) into \( z \), and by construction, so
that \( (\alpha(w)(t),\xi(t)) \) is in \( O \) for all \( t \in [0,T] \).\]
