\textbf{A B S T R A C T}

Contraction theory is a powerful tool for proving asymptotic properties of nonlinear dynamical systems including convergence to an attractor and entrainment to a periodic excitation. We consider three generalizations of contraction with respect to a norm that allow contraction to take place after small transients in time and/or amplitude. These generalized contractive systems (GCSs) are useful for several reasons. First, we show that there exist simple and checkable conditions guaranteeing that a system is a GCS, and demonstrate their usefulness using several models from systems biology. Second, allowing small transients does not destroy the important asymptotic properties of contractive systems like convergence to a unique equilibrium point, if it exists, and entrainment to a periodic excitation. Third, in some cases as we change the parameters in a contractive system it becomes a GCS just before it looses contractivity with respect to a norm. In this respect, generalized contractivity is the analogue of marginal stability in Lyapunov stability theory.

\section{1. Introduction}

Differential analysis is based on studying the time evolution of the distance between trajectories emanating from different initial conditions. A dynamical system is called contractive if any two trajectories converge to one other at an exponential rate. This implies many desirable properties including convergence to a unique attractor (if it exists), and entrainment to periodic excitations (Aminzare & Sontag, 2014; Lohmiller & Slotine, 1998; Russo, di Bernardo, & Sontag, 2010). Contraction theory proved to be a powerful tool for analyzing nonlinear dynamical systems, with applications in control theory (Lohmiller & Slotine, 2000), observer design (Bonnabel, Astolfi, & Sepulchre, 2011), synchronization of coupled oscillators (Wang & Slotine, 2005), and more. Recent extensions include: the notion of partial contraction (Slotine, 2003), analyzing networks of interacting agents using contraction theory (Arcak, 2011; Russo, di Bernardo, & Sontag, 2013), a Lyapunov-like characterization of incremental stability (Angeli, 2002), and a LaSalle-type principle for contractive systems (Formi & Sepulchre, 2014). There is also a growing interest in design techniques providing controllers that render control systems contractive or incrementally stable; see, e.g., Zamani, van de Wouw, and Majumdar (2013) and the references therein, and also the incremental ISS condition in Desoer and Haneda (1972).

A contractive system with added diffusion terms or random noise still satisfies certain asymptotic properties (Aminzare & Sontag, 2013; Pham, Tabareau, & Slotine, 2009). In this respect, contraction is a robust property.

In this note, we introduce three forms of generalized contractive systems (GCSs). These are motivated by requiring contraction with respect to a norm to take place only after arbitrarily small transients in time and/or amplitude. Our work was motivated by certain models from systems biology that are not contractive with respect to any (fixed) norm, yet are “almost” contractive. One example is where contraction is lost only on the boundary of the state space, but trajectories emanating from this boundary “immediately” enter the interior of the state space. Thus, we have contraction after an arbitrarily short time transient. The goal of the note is to rigorously define these forms of contraction, study its properties, and derive sufficient conditions for its existence. The contribution...
of this note is thus two-fold: the theoretical study of this type of contraction after an infinitesimal transient, and using this notion to prove important asymptotic properties in applications. Indeed, contraction is usually used to prove asymptotic properties, and thus allowing (arbitrarily small) transients seems reasonable. We provide several sufficient conditions for a system to be a GCS. These conditions are checkable, and we demonstrate their usefulness using several examples of systems that are not contractive with respect to any norm, yet are GCSs.

In some cases, as we change the parameters in a contractive system it becomes a GCS just before it loses contractivity. In this respect, a GCS is the analogue of marginal stability in Lyapunov stability theory.

We begin with a brief review of some ideas from contraction theory. See Soderlind (2006), Joffrouy (2005) and Rüffer, van de Wouw, and Mueller (2013) for more details, including the historic development of contraction theory, and the relation to other notions.

Consider the time-varying system

$$\dot{x} = f(t, x),$$

(1)

with the state $x$ evolving on a positively invariant convex set $\Omega \subseteq \mathbb{R}^n$. We assume that $f(t, x)$ is differentiable with respect to $x$, and that both $f(t, x)$ and $f(t, x) := \frac{df}{dt}(t, x)$ are continuous in $(t, x)$. Let $x(t, t_0, x_0)$ denote the solution of (1) at time $t \geq t_0$ with $x(t_0) = x_0$ (for the sake of simplicity, we assume from here on that $x(t_0, x_0)$ exists and is unique for all $t \geq t_0 \geq 0$ and all $x_0 \in \Omega$).

We say that (1) is **contractive** on $\Omega$ with respect to a norm $\| \cdot \| : \mathbb{R}^n \to \mathbb{R}_+$ if there exists $c > 0$ such that

$$\| x(t_2, t_1, a) - x(t_2, t_1, b) \| \leq \exp(-c(t_2 - t_1)) \| a - b \|$$

(2)

for all $t_2 \geq t_1 \geq 0$ and all $a, b \in \mathbb{R}^n$. In other words, any two trajectories contract to one another at an exponential rate. This implies in particular that the initial condition is “quickly forgotten”. Note that Lohmiller and Slotine (1998) provide a more general and intrinsic definition, where contraction is with respect to a time- and state-dependent metric $M(t, x)$. Simpson-Porco and Bullo (2014) provide a general treatment of contraction on a Riemannian manifold; see also Lewis (1949). Some of the results below may be stated using this more general framework. But, for a given dynamical system finding such a metric may be difficult; see e.g., Ayliward, Parrilo, and Slotine (2008) for an algorithm for finding such contraction metrics using sum-of-squares programming.

Another extension of contraction is incremental stability (Angeli, 2002). Our approach is based on the fact that there exists a simple sufficient condition guaranteeing (2), so generalizing (2) appropriately leads to checkable sufficient conditions for a system to be a GCS. Another advantage of our approach is that a GCS retains the important property of entrainment to periodic signals.

Recall that a vector norm $\| \cdot \| : \mathbb{R}^n \to \mathbb{R}_+$ induces a matrix measure $\mu : \mathbb{R}^{n \times n} \to \mathbb{R}_+$ defined by $\mu(A) := \lim_{\| \epsilon \| \to 0} \frac{1}{2} \| (\| \epsilon \| + \epsilon A) I_n - A \|$. A standard approach for proving (2) is based on bounding some matrix measure of the Jacobian. Indeed, it is well-known (Ruissolo et al., 2010) that if there exist a vector norm $\| \cdot \|$ and $c > 0$ such that the induced matrix measure $\mu : \mathbb{R}^{n \times n} \to \mathbb{R}$ satisfies $\mu(f(t, x)) \leq -c$, for all $t_2 \geq t_1 \geq 0$ and all $x \in \Omega$ then (2) holds. (This is in fact a particular case of using a Lyapunov–Finster function to prove contraction (Formi & Sepulchre, 2014).)

It is well-known (Vidyasagar, 1978, Ch. 3) that the matrix measure induced by the $L_1$ vector norm is

$$\mu_1(A) = \max \{c_1(A), \ldots, c_n(A)\},$$

where

$$c_j(A) := A_j + \sum_{i \neq j} |A_{ij}|,$$

i.e., the sum of the entries in column $j$ of $A$, with no diagonal elements replaced by their absolute values. The matrix measure induced by the $L_\infty$ norm is $\mu_\infty(A) = \max \{d_1(A), \ldots, d_n(A)\}$, where

$$d_j(A) := A_j + \sum_{i \neq j} |A_{ij}|,$$

i.e., the sum of the entries in row $j$ of $A$, with no diagonal elements replaced by their absolute values.

Often it is useful to work with scaled norms. Let $\| \cdot \|_v$ be some vector norm, and let $\mu_v : \mathbb{R}^{n \times n} \to \mathbb{R}$ denote its induced matrix measure. If $P \in \mathbb{R}^{n \times n}$ is an invertible matrix, and $\| \cdot \|_v : \mathbb{R}^n \to \mathbb{R}_+$ is the vector norm defined by $\| z \|_v := \| P z \|_v$, then the induced matrix measure is $\mu_{v, P}(A) = \mu_v(P A P^{-1})$.

One important implication of contraction is *entrainment* to a periodic excitation. Recall that $f : \mathbb{R}_+ \times \Omega \to \mathbb{R}^n$ is called $T$-periodic if $f(t, x) = f(t + T, x)$ for all $t \geq 0$ and all $x \in \Omega$. Note that for the system $\dot{x}(t) = f(x(t), x(t))$, with $u$ an input (or excitation) function, $f$ will be $T$-periodic if $u$ is a $T$-periodic function. It is well-known (Lohmiller & Slotine, 1998; Russo et al., 2010) that if (1) is contractive and $f$ is $T$-periodic then for any $t_1 \geq 0$ there exists a unique periodic solution $x : [t_1, \infty) \to \Omega$ of (1), of period $T$, and every trajectory converges to $x$. Entrainment is important in various applications ranging from biological systems (Margaliot, Sonntag, & Tuller, 2014; Russo et al., 2010) to the stability of a power grid (Dorfler & Bullo, 2012). Note that for the particular case where $f$ is time-invariant, this implies that if $\Omega$ contains an equilibrium point $e$ then it is unique and all trajectories converge to it.

The remainder of this note is organized as follows. Section 2 presents three generalizations of (2). Section 3 details sufficient conditions for their existence, and describes their implications. Due to space limitations, the proofs of all the results are placed at: http://arxiv.org/abs/1506.06613.

2. Definitions of contraction after small transients

We begin by defining three generalizations of (2):

**Definition 1.** The time-varying system (1) is said to be:

- **contractive after a small overshoot and short transient** (SOST) on $\Omega$ w.r.t. a norm $\| \cdot \| : \mathbb{R}^n \to \mathbb{R}_+$ if for each $\epsilon > 0$ and each $\tau > 0$ there exists $\ell = \ell(\epsilon, \tau) > 0$ such that
  $$\| x(t_2 + \tau, t_1, a) - x(t_2 + \tau, t_1, b) \| \leq (1 + \exp(-\ell)) |a - b|$$
  for all $t_2 \geq t_1 \geq 0$ and all $a, b \in \Omega$.

- **contractive after a small overshoot** (SO) on $\Omega$ w.r.t. a norm $\| \cdot \| : \mathbb{R}^n \to \mathbb{R}_+$, if for each $\epsilon > 0$ there exists $\ell = \ell(\epsilon) > 0$ such that
  $$\| x(t_2 + \tau, t_1, a) - x(t_2, t_1, b) \| \leq (1 + \exp(-\ell)) |a - b|$$
  for all $t_2 \geq t_1 \geq 0$ and all $a, b \in \Omega$.

- **contractive after a short transient** (ST) on $\Omega$ w.r.t. a norm $\| \cdot \| : \mathbb{R}^n \to \mathbb{R}_+$, if for each $\tau > 0$ there exists $\ell = \ell(\tau) > 0$ such that
  $$\| x(t_2 + \tau, t_1, a) - x(t_2, t_1, b) \| \leq \exp(-\ell) |a - b|$$
  for all $t_2 \geq t_1 \geq 0$ and all $a, b \in \Omega$.

The definition of SOST is motivated by requiring contraction at an exponential rate, but only after an (arbitrarily small) time $\tau$, and with an (arbitrarily small) overshoot ($1 + \epsilon$). However, as we will see below when the convergence rate $\ell$ may depend on $\epsilon$ a somewhat richer behavior may occur. The definition of SO is similar to that of SOST, yet now the convergence rate $\ell$ depends only on $\epsilon$. 

M. Margaliot et al. / Automatica 67 (2016) 178–184

179
and there is no time transient \( \tau \) (i.e., \( \tau = 0 \)). In other words, SO is a uniform (in \( \tau \)) version of SOST. The third definition, ST, allows the contraction to "kick in" only after a time transient of length \( \tau \).

It is clear that every contractive system is SOST, SO, and ST. Thus, all these notions are generalizations of contraction. Also, both SO and ST imply SOST and, as we will see below, under a mild technical condition on (1) SO and SOST are equivalent. Fig. 1 summarizes the relations between these GCSs (as well as other notions defined below).

One motivation for these definitions stems from the fact that important applications of contraction are in proving asymptotic properties. For example, proving that what happens as \( t \to \infty \), and so it seems natural to generalize contraction in a way that allows initial transients in time and/or amplitude.

The next simple example demonstrates a system that does not satisfy (2), but is a GCS.

**Example 1.** Consider the scalar time-varying system \( \dot{x}(t) = -\alpha(t)x(t) \), with the state \( x \) evolving on \( \Omega := [-1, 1] \), and \( \alpha : \mathbb{R} \to \mathbb{R} \) is a class K function (i.e. \( \alpha \) is continuous and strictly increasing, with \( \alpha(0) = 0 \)). It is straightforward to show that this system does not satisfy (2) w.r.t. any norm (note that the Jacobian \( J(t) = -\alpha(t) \) satisfies \( J(0) = 0 \)), yet it is ST, with \( \ell(t) = \alpha(t) > 0 \), for any given \( t > 0 \).

3. Main results

The next three subsections study the three forms of GCSs defined above.

**Contraction after a small overshoot and short transient**

Just like contraction, SOST implies entrainment to a periodic excitation.

**Proposition 1.** Suppose that the time-varying system (1), with state \( x \) evolving on a compact and convex state-space \( \Omega \subseteq \mathbb{R}^n \), is SOST, and that the vector field \( f \) is \( T \)-periodic. Then for any \( t_0 \geq 0 \) it admits a unique periodic solution \( \gamma : [t_0, \infty) \to \Omega \) with period \( T \), and \( x(t, t_0, a) \) converges to \( \gamma \) for any \( a \in \Omega \).

Since both SO and ST imply SOST, Proposition 1 holds for all three forms of GCSs.

Our next goal is to derive a sufficient condition for SOST. One may naturally expect that if (1) is contractive w.r.t. a set of norms \( |\cdot|_\zeta \), with, say \( \zeta \in (0, 1] \), and that \( \lim_{\tau \to 0} |\cdot|_\zeta = |\cdot| \), then (1) is a GCS w.r.t. the norm \( |\cdot| \). In fact, this can be further generalized by requiring (1) to be contractive w.r.t. \( |\cdot|_\zeta \) only on suitable subset \( \Omega_\tau \) of the state-space. This leads to the following definition.

**Definition 2.** System (1) is said to be nested contractive (NC) on \( \Omega \) with respect to a norm \( |\cdot| \) if there exist convex sets \( \Omega_\tau \subseteq \Omega \), and norms \( |\cdot|_\zeta : \mathbb{R}^n \to \mathbb{R}_+ \), where \( \zeta \in (0, 1] \), such that the following conditions hold.

(a) \( \cup_{\tau \in (0,1/2]} \Omega_\tau = \Omega \), and \( \Omega_{\tau_1} \subseteq \Omega_{\tau_2} \), for all \( \tau_1 \geq \tau_2 \).
(b) For every \( \tau > 0 \) there exists \( \zeta = \zeta(\tau) \in (0, 1/2] \), with \( \zeta(\tau) \to 0 \) as \( \tau \to 0 \), such that for every \( a \in \Omega \) and every \( t_1 \geq 0 \)

\[ x(t, t_1, a) \in \Omega_{\tau} \quad \text{for all } t \geq t_1 + \tau, \]

and (1) is contractive on \( \Omega_\tau \) with respect to \( |\cdot|_\zeta \).
(c) The norms \( |\cdot|_\zeta \) converge to \( |\cdot| \) as \( \zeta \to 0 \), i.e., for every \( \zeta > 0 \) there exists \( s = s(\zeta) > 0 \), with \( s(\zeta) \to 0 \) as \( \zeta \to 0 \), such that \( (1 - s)|y| \leq |y|_\zeta \leq (1 + s)|y| \), for all \( y \in \Omega \).

Eq. (7) means that after an arbitrarily short time every trajectory enters and remains in a subset \( \Omega_\tau \) of the state space on which we have contraction with respect to \( |\cdot|_\zeta \). We can now state the main result in this subsection.

**Theorem 1.** If the system (1) is NC w.r.t. the norm \( |\cdot| \) then it is SOST w.r.t. the norm \( |\cdot| \).

The next example demonstrates Theorem 1. It also shows that as we change the parameters in a contractive system, it may become a GCS when it hits the "verge" of contraction (as defined in (2)). This is reminiscent of an asymptotically stable system that becomes marginally stable as it looses stability.

**Example 2.** Consider the system

\[ \dot{x}_1 = g(x_0) - \alpha_1x_1, \]
\[ \dot{x}_2 = x_1 - \alpha_2x_2, \]
\[ \dot{x}_3 = x_2 - \alpha_3x_3, \]
\[ \vdots \]
\[ \dot{x}_n = x_{n-1} - \alpha_nx_n, \]

where \( \alpha_i > 0 \), and \( g(u) := \frac{1+u}{k+u} \), with \( k > 1 \). This models a simple biochemical feedback control circuit for protein synthesis in the cell (Smith, 1995, Ch. 4). The \( x_i \)s represent concentrations of various macro-molecules in the cell and therefore must be non-negative. It is straightforward to verify that \( x(0) \in \mathbb{R}^n_+ \) implies that \( x(t) \in \mathbb{R}^n_+ \) for all \( t \geq 0 \).

Let \( \alpha := \prod_{i=1}^n \alpha_i \), and for \( \epsilon > 0 \) let

\[ D_\epsilon := \text{diag}(1, 1, \alpha_1 - \epsilon, \ldots, \prod_{i=1}^{n-1} (\alpha_i - \epsilon)). \]

If

\[ k - 1 < ak^2 \]

then (7) is contractive on \( \mathbb{R}^n_+ \) w.r.t. the scaled norm \( |\cdot|_{D_\epsilon} \), for all \( \epsilon > 0 \) sufficiently small. If \( k - 1 = ak^2 \) then (7) does not satisfy (2), w.r.t. any norm, on \( \mathbb{R}^n_+ \), yet it is SOST on \( \mathbb{R}^n_+ \) w.r.t. the norm \( |\cdot|_{D_\epsilon} \).

Note that for all \( x \in \mathbb{R}^n_+ \),

\[ g'(x_0) = \frac{k - 1}{(k + x_0)^2} \leq \frac{k - 1}{k^2} = g'(0). \]

Thus (9) implies that the system satisfies (2) if and only if the "total dissipation" \( \alpha_i \) is strictly larger than \( g'(0) \).

Using the fact that \( g(u) < 1 \) for all \( u \geq 0 \) it is straightforward to show that the set \( \Omega_{\tau} := r([0, \alpha_1^{-1}] \times [0, (\alpha_2^{-1})^{-1}] \times \cdots \times \]

\[ \times [0, (\alpha_n^{-1})^{-1}]) \subset \Omega_{\tau} \]

\[ \cup_{\tau \in (0,1/2]} \Omega_\tau = \Omega \], and \( \Omega_{\tau_1} \subseteq \Omega_{\tau_2} \), for all \( \tau_1 \geq \tau_2 \).

1 Due to space limitations, the details of the analysis are placed at: http://arxiv.org/abs/1506.06613.
\[0, \alpha^{-1}]\} is an invariant set of the dynamics for all \( r \geq 1 \). Thus, (7), with \( k = 1 \leq ak^2 \), admits a unique equilibrium point \( e \in \Omega \), and \( \lim_{y \to \infty} x(t, a) = e \), for all \( a \in \mathbb{R}^n \). This property also follows from a more general result (Smith, 1995, Prop. 4.2.1) that is proved using the theory of irreducible cooperative dynamical systems. Yet the GCS approach leads to new insights. For example, it implies that the distance between trajectories can only decrease, and can also be used to prove entrainment to suitable generalizations of (7) that include periodically-varying inputs.

Cells often respond to external stimulus by modification of proteins. One mechanism for this is phoshorelay (also called phospho-transfer) in which a phosphate group is transferred through a serial chain of proteins from an initial histidine kinase (HK) down to a final response regulator (RR). The next example uses Theorem 1 to analyze a model for phoshorelay from Casiskas-Nagy, Cardelli, and Soyer (2011).

**Example 3.** Consider the system

\[
\begin{align*}
\dot{x}_1 &= (p_1 - x_1)c - \eta_1 x_1(p_2 - x_2), \\
\dot{x}_2 &= \eta_2 x_1(p_2 - x_2) - \eta_2 x_2(p_3 - x_3), \\
&\vdots \\
\dot{x}_{n-1} &= \eta_{n-2} x_{n-2}(p_{n-1} - x_{n-1}) - \eta_{n-1} x_{n-1}(p_n - x_n), \\
\dot{x}_n &= \eta_{n-1} x_{n-1}(p_n - x_n) - \eta_n x_n,
\end{align*}
\]  

(10)

where \( \eta_i, p_i > 0 \), and \( c : [t_i, \infty) \to \mathbb{R} \). In the context of phoshorelay, \( c(t) \) is the strength at time \( t \) of the stimulus activating the HK, \( x_i(t) \) is the concentration of the phosphorylated form of the protein at the \( i \)th layer at time \( t \), and \( p_i \) denotes the total protein concentration at that layer. Note that \( \eta_n x_n \) is the flow of the phosphate group to an external receptor molecule.

In the particular case where \( p_1 = 1 \) for all \( i \) (9) becomes the ribosome flow model (RFM) (Reuveni, Melijison, Kupiec, Ruppin, & Tuller, 2011). This is the mean-field approximation of an important model from non-equilibrium statistical physics called the totally asymmetric simple exclusion process (TASEP) (Blythe & Evans, 2007). In the RFM, \( x_i \in [0, 1] \) is the normalized occupancy at site \( i \), where \( x_i = 0 = \{x_i = 1\} \) means that site \( i \) is completely free [full], and \( \eta_i \) is the capacity of the link that connects site \( i \) to site \( i+1 \).

This has been used to model mRNA translation, where every site corresponds to a group of codons on the mRNA strand, \( x_i(t) \) is the normalized occupancy of ribosomes at site \( i \) at time \( t \), \( c(t) \) is the initiation rate at time \( t \), and \( \eta_i \) is the elongation rate from site \( i \) to site \( i+1 \).

Our original motivation for generalizing (2) was to prove entrainment in the RFM (Margaliot et al., 2014). For more results on the RFM, see Margaliot and Tuller (2012a,b), 2013, Poker, Zarai, Margaliot, and Tuller (2014) and Zarai, Margaliot, and Tuller (2013).

Assume that there exists \( n_0 > 0 \) such that \( c(t) \geq n_0 \) for all \( t \geq t_1 \). Let \( \Omega := [0, p_1] \times \cdots \times [0, p_n] \) denote the state-space of (9). Eq. (9) does not satisfy (2), w.r.t. any norm, on \( \Omega \), yet it is SOST on \( \Omega \) w.r.t. the \( L_1 \) norm.

Considering Theorem 1 in the special case where all the sets \( \Omega_c \) in Definition 2 are equal to \( \Omega \) yields the following result.

**Corollary 1.** Suppose that (1) is contractive on \( \Omega \) w.r.t. a set of norms \( \{\|\cdot\|_r, r \in (0, 1/2]\}, \) and that condition (c) in Definition 2 holds. Then (1) is SOST on \( \Omega \) w.r.t. \( \cdot \).

**Corollary 1** may be useful in cases where some matrix measure of the Jacobian \( J \) of (1) turns out to be non positive on \( \Omega \), but not strictly negative, suggesting that the system is “on the verge” of satisfying (2). The next result demonstrates this for the time-invariant system

\[
\dot{x} = f(x),
\]

(11)

and the particular case of the matrix measure \( \mu_1 : \mathbb{R}^{n \times n} \to \mathbb{R} \) induced by the \( L_1 \) norm. Recall that this is given by (3) with the \( c_i \)s defined in (4).

**Proposition 2.** Consider the Jacobian \( f(\cdot) : \Omega \to \mathbb{R}^{n \times n} \) of the time-invariant system (11). Suppose that \( \Omega \) is compact and that the set \( \{1, \ldots, n\} \) can be divided into two non-empty disjoint sets \( S_0 \) and \( S_\infty \) such that the following properties hold for all \( x \in \Omega \):

(1) for any \( k \in S_\infty \), \( c_k(f(x)) \leq 0 \);
(2) for any \( j \in S_\infty \), \( c_j(f(x)) < 0 \);
(3) for any \( i \in S_0 \) there exists an index \( z = z(i) \in S_\infty \) such that \( J_z(x) > 0 \).

Then (11) is SOST on \( \Omega \) w.r.t. the \( L_1 \) norm.

The proof of Proposition 2 is based on the following idea. By compactness of \( \Omega \), there exists \( \delta > 0 \) such that \( c_j(f(x)) < -\delta \), for all \( j \in S_\infty \) and all \( x \in \Omega \).

The conditions stated in the proposition imply that there exists a diagonal matrix \( P \) such that \( c_k(P^{-1}) < 0 \) for all \( k \in S_\infty \). Furthermore, there exists such a \( P \) with diagonal entries arbitrarily close to \( 0 \), so \( c_k(P^{-1}) < -\delta/2 \) for all \( j \in S_\infty \) and \( k \in S_\infty \) such that \( \mu_1(\{ J_z(x) \}) > 0 \) for all \( x \in \Omega \).

**Corollary 1** implies SOST. Note that this implies that the compactness assumption may be dropped if for example it is known that (12) holds.

**Example 4.** Consider the system:

\[
\begin{align*}
\dot{x} &= -\delta x + k_1 y - k_2 (x_t - y)x, \\
\dot{y} &= -k_3 y + k_4 (x_t - y)x,
\end{align*}
\]

(13)

where \( \delta, k_1, k_2, x_t > 0 \), and \( \Omega := [0, \infty) \times [0, x_t] \). This is a basic model for a transcriptional module that is ubiquitous in both biology and synthetic biology (see, e.g., Del Vecchio, Ninfa, & Sontag, 2008, Russo et al., 2010). Here \( x(t) \) is the concentration at time \( t \) of a transcriptional factor \( X \) that regulates a downstream transcriptional module by binding to a promoter with concentration \( c(t) \) yielding a protein–promoter complex \( Y \) with concentration \( y(t) \). The binding reaction is reversible with binding and dissociation rates \( k_2 \) and \( k_3 \), respectively. The linear degradation rate of \( X \) is \( \delta \), and as the promoter is not subject to decay, its total concentration, \( x_t \), is conserved, so \( e(t) = e_t - y(t) \).

Russo et al. (2010) have shown that (12) is contractive w.r.t. a certain weighted \( L_1 \) norm. The Jacobian of (12) is \( J = \begin{bmatrix} -k_2 (x_t - x) - k_3 x & k_2 x \\ k_2 (x_t - y) - k_1 & -k_2 x \end{bmatrix} \), and all the properties in Proposition 2 hold with \( S_\infty = \{1\} \) and \( S_\infty = \{2\} \). Indeed, \( J_{z_2} = k_1 + k_2 x > k_1 > 0 \) for all \( x \) and \( y(t) \) in \( \Omega \). Thus, (12) is SOST on \( \Omega \) w.r.t. the \( L_1 \) norm.

Arguing as in the proof of Proposition 2 for the matrix measure \( \mu_\infty \) induced by the \( L_\infty \) norm (see (5)) yields the following result.

**Proposition 3.** Consider the Jacobian \( f(\cdot) : \Omega \to \mathbb{R}^{n \times n} \) of the time-invariant system (11). Suppose that \( \Omega \) is compact and that the set \( \{1, \ldots, n\} \) can be divided into two non-empty disjoint sets \( S_0 \) and \( S_\infty \) such that the following properties hold for all \( x \in \Omega \):

(1) \( d(f(x)) \leq 0 \) for all \( j \in S_0 \);
(2) \( d(f(x)) < 0 \) for all \( k \in S_\infty \);
(3) for any \( j \in S_0 \) there exists an index \( z = z(j) \in S_\infty \) such that \( J_z(x) \neq 0 \).

Then (11) is SOST on \( \Omega \) w.r.t. the \( L_\infty \) norm.

Contraction after a short overshoot

A natural question is under what conditions SO and SOST are equivalent. To address this issue, we introduce the following definition.

Definition 3. We say that (1) is weakly expansive (WE) if for each \( \delta > 0 \) there exists \( \tau_0 > 0 \) such that for all \( a, b \in \Omega \) and all \( t \geq 0 \),
\[
|x(t, a) - x(t, b)| \leq (1 + \delta)|a - b|,
\]
for all \( t \in [t_0, t_0 + \tau_0] \).

Proposition 4. Suppose that (1) is WE. Then (1) is SOST if and only if it is SO.

Remark 1. Suppose that \( f \) in (1) is Lipschitz globally in \( \Omega \) uniformly in \( t \), i.e., there exists \( L > 0 \) such that \(|f(t, x) - f(t, y)| \leq L|x - y|\), for all \( x, y \in \Omega, t \geq 0 \). Then by Gronwall’s Lemma (see, e.g., Sontag, 1998, Appendix C), \(|x(t, a) - x(t, b)| \leq \exp(\int_{t_0}^{t} L(t - \tau_0)|a - b|, \) for all \( t \geq t_0 > 0 \), and this implies that (14) holds for \( \tau_0 := \frac{1}{L} \ln(1 + \delta) > 0 \). In particular, if \( \Omega \) is compact and \( f \) is periodic in \( t \) then WE holds under rather weak continuity arguments on \( f \).

Contraction after a short transient

For time-invariant systems whose state evolves on a convex and compact set it is possible to give a simple sufficient condition for ST. Let \( \text{Int}(S) \) denote the interior [boundary] of a set \( S \). We require the following definitions.

Definition 4. We say that (1) is non expansive (NE) w.r.t. a norm \( \cdot \) if for all \( a, b \in \Omega \) and all \( \tau_0 > 0 \),
\[
|x(x, a) - x(x, b)| \leq |a - b|,
\]
for all \( t \in [t_0, t_0 + \tau_0] \).

We say that (1) is weakly contractive (WC) if (15) holds with \( \leq \) replaced by \( < \).

Definition 5. The time-invariant system (11) with the state \( x \) evolving on a compact and convex set \( \Omega \subset \mathbb{R}^n \), is said to be interior contractive (IC) w.r.t. a norm \( \cdot \) if for all \( a, b \in \Omega \) and all \( \tau_0 > 0 \),
\[
|x(x, a) - x(x, b)| \leq |a - b|,
\]
for all \( t \in [t_0, t_0 + \tau_0] \).

We say that (1) is weakly contractive (WC) if (15) holds with \( \leq \) replaced by \( < \).

Theorem 2. If the system (11) is IC w.r.t. a norm \( \cdot \) then it is ST w.r.t. \( \cdot \).

The proof of this result is based on showing that IC implies that for each \( \tau > 0 \) there exists \( d = d(\tau) > 0 \) such that \( \text{dist}(x(t, a), \partial \Omega) \geq d \), for all \( x_0 \in \Omega \) and all \( t \geq \tau \), and then using this to conclude that for any \( t \geq \tau \) all the trajectories of the system are contained in a convex and compact set \( D \subset \text{Int}(\Omega) \). In this set the system is contractive with rate \( c := \max_{a,b} \mu(J(x)) < 0 \). The next example, that is a variation of a system studied by Russo et al. (2010), demonstrates this reasoning.

Example 5. Consider a transcriptional factor \( X \) that regulates a downstream transcriptional module by irreversibly binding, at a rate \( k_2 > 0 \), to a promoter yielding a protein–promoter complex \( Y \). The promoter is not subject to decay, so its total concentration, denoted by \( \tau_0 > 0 \), is conserved. Assume also that \( X \) is obtained from an inactive form \( X_0 \), for example through a phosphorylation reaction that is catalyzed by a kinase with abundance \( u(t) \) satisfying \( u(t) \geq u_0 > 0 \) for all \( t \geq 0 \). The sum of the concentrations of \( X_0, X \), and \( Y \) is constant, denoted by \( z_t \), with \( z_t > \epsilon_t \). Letting \( x_1(t), x_2(t) \) denote the concentrations of \( X, Y \) at time \( t \) yields the model
\[
\begin{align*}
\dot{x}_1 &= (\epsilon_t - x_1 + x_2)u - \delta x_1 - k_2(\epsilon_t - x_2)x_1, \\
\dot{x}_2 &= k_2(\epsilon_t - x_2)x_1,
\end{align*}
\]
(17)
with the state evolving on \( \Omega := [0, z_t] \times [0, \epsilon_t] \). Here \( \delta \geq 0 \) is the dephosphorylation rate \( X \rightarrow X_0 \). Let \( P := \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} \) and consider the matrix measure \( \mu_{\infty, P} \). Let \( J := P^{-1}1 \). A calculation yields \( J = \frac{1}{\epsilon} \), so that \( d(J) = -2u - \delta - |\delta| \leq -u_0 < 0 \), and
\[
d_2(J) = k_2(x_2 - x_1 > \epsilon_t) + k_2(\epsilon_t - x_2) - k_2(x_2 - x_1 > \epsilon_t)
\]
(18)
Letting \( S := [0] \times [0, \epsilon_t] \), we conclude that \( \mu_{\infty, P} < 0 \) for all \( x \in \Omega \setminus S \). For any \( x \in S \), \( \dot{x}_1 = (z_1 - x_2)u \geq (z_1 - \epsilon_t)u_0 > 0 \), and as in the proof of Theorem 2, we conclude that for any \( \tau > 0 \) there exists \( d = d(\tau) > 0 \) such that \( x_1(t, a) \geq d \), for all \( a \in \Omega \) and all \( t \geq \tau \). In other words, after time \( \tau \) all the trajectories are contained in the closed and convex set \( D = D(\tau) := [0, z_1] \times [0, \epsilon_t] \). Letting \( c := c(t) = \max_{a,b} \mu_{\infty, P}(J(x)) \) yields \( c < 0 \) and \( J(t + \tau, a) - \epsilon(t + \tau, b) \leq \exp(-ct)|a - b|_{-\infty, P} \) for all \( a, b \in \Omega \) and all \( t > 0 \), so (16) is ST w.r.t. \( \cdot \).

As noted above, the introduction of GCS is motivated by the idea that contraction is used to prove asymptotic results, so allowing initial transients should increase the class of systems that can be analyzed while still allowing to prove asymptotic results. The next result demonstrates this.

Corollary 2. If (11) is IC with respect to some norm then it admits a unique equilibrium point \( e \in \text{Int}(\Omega) \), and \( \lim_{t \rightarrow \infty} x(t, a) = \epsilon \) for all \( a \in \Omega \).

Remark 2. Consider the variational system (see, e.g., Forni & Sepulchre, 2014) associated with (11),
\[
\dot{x} = f(x),
\]
(19)
Our proof of Corollary 2 is based on Theorem 2. An alternative proof is possible, using the Lyapunov–Finsler function \( V(x, \delta x) := |\delta x| \), where \( |\cdot| : \mathbb{R}^n \rightarrow \mathbb{R} \) is the vector norm corresponding to the matrix measure \( \mu \) in (16), and the LaSalle invariance principle described in Forni and Sepulchre (2014).

Contraction can be characterized using a Lyapunov–Finsler function (Forni & Sepulchre, 2014). The next result describes a similar characterization for ST. For simplicity, we state this for the time–invariant system (11).

Proposition 5. The following two conditions are equivalent.

(a) For any \( \tau > 0 \) there exists \( d = d(\tau) > 0 \) such that for any \( a, b \in \Omega \) and any \( c \) on the line connecting \( a \) and \( b \) the solution of (17) with \( x(0) = c \) and \( \delta x(0) = b - a \) satisfies \( |\delta x(t + \tau)| \leq \exp(-c\tau)|\delta x(0)| \), for all \( t \geq 0 \).

Note that the latter condition implies that the function \( V(x, \delta x) := |\delta x| \) is a generalized Lyapunov–Finsler function in the following sense. For any \( \tau > 0 \) there exists \( \ell = \ell(\tau) > 0 \) such that along solutions of the variational system: \( V(x(t + \tau, x(0)), \delta x(t + \tau, \delta x(0), x(0))) \leq \exp(-c\tau)V(x(0), \delta x(0)) \), for all \( t \geq 0 \).
It is straightforward to show that each of the three generalizations of contraction in Definition 1 implies that (1) is NE. One may perhaps expect that any of the three generalizations of contraction in Definition 1 also implies WC. Indeed, ST does imply WC, because $|x(s_j, s_1) - b|/|b - a| < 1$ for all $0 < s_j < s_1$ if ST holds (simply apply the definition with $t_1 = s_j, t_2 = s_1/2 > 0$, and $t_3 = s_1 + t_2$ in (6)). However, the next example shows that SO does not imply WC.

**Example 6.** Consider the scalar system

$$\dot{x} = \begin{cases} -2x, & 0 \leq |x| < 1/2, \\ -x, & 1/2 \leq |x| < 1, \end{cases}$$

with $x$ evolving on $\Omega := [-1, 1]$. Clearly, this system is not WC. However, it is not difficult to show that it satisfies the definition of SO with $\ell = \ell(x) = \min(1 + |x|)$. Thus, Example 1 summarizes the relations between the various contraction notions.

Michael Margaliot received his Ph.D. (summa cum laude) in Control Theory from the Dept. of Elect. Eng.-Systems at Tel Aviv University (TAU) in 1999. He is currently a Professor and Chair of this department. He also serves as the treasurer of the Israel Association for Automatic Control and as an Associate Editor of IEEE Transactions on Automatic Control. He received the Dean’s Award for excellence in teaching at the School of Elect. Eng. for the academic year 2010–2011, and was elected to the Rector’s 100 Club (list of 100 outstanding teachers at TAU) in 2014. His research interests include fuzzy logic and control, Boolean control networks, stability analysis of switched systems, optimal control theory, and systems biology.

Eduardo D. Sontag received his undergraduate degree in Mathematics from the University of Buenos Aires in 1972, and his Ph.D. in Mathematics from the University of Florida in 1976, working under Rudolf E. Kalman. Since 1977, he has been at Rutgers University, where he is a Distinguished Professor in the Department of Mathematics. He is also a Member of the Rutgers Cancer Institute of New Jersey as well as of the graduate faculties of the Departments of Computer Science and of Electrical and Computer Engineering. He currently serves as head of the Undergraduate Biomathematics Interdisciplinary Major, Director of the Graduate Program in Quantitative Biomedicine, and Director of the Center for Quantitative Biology.

His current research interests are broadly in applied mathematics, and specifically in systems biology, dynamical systems, and feedback control theory. In the 1980s and 1990s, he introduced new tools for analyzing the effect of external inputs on the stability of nonlinear systems (“input to state stability”) and for feedback design (“control-Lyapunov functions”), both of which have been widely adopted as paradigms in engineering research and education. He also developed the early theory of hybrid (discrete/continuous) control, and worked on learning theory applied to neural processing systems as well as in foundations of analog computing. Starting around 1999, his work has turned in large part to developing basic theoretical aspects of biological signal transduction pathways and gene networks, as well as collaborations with a range of experimental and computational biological labs dealing with cell cycle modeling, development, cancer progression, infectious diseases, physiology, synthetic biology, and other topics. He has published about 500 papers in fields ranging from Control Theory and Theoretical Computer Science to Cell Biology, with over 33,000 citations and a google scholar h-index of 81. He is a Fellow of the IEEE, AMS, SIAM, and IFAC. He was awarded the Reid Prize by SIAM in 2001, the Bode Prize in 2002 and the Control Systems Field Award in 2011 from IEEE, and the 2002 Board of Trustees Award for Excellence in Research and the 2005 Teacher/ Scholar Award from Rutgers.
Tamir Tuller received B.Sc. degrees in Electrical Engineering, Mechanical Engineering and Computer Science from Tel Aviv University (TAU), Tel Aviv, Israel; the MSc degree in Electrical Engineering from the Technion-Israel Institute of Technology, Haifa, Israel, and M.Sc. studies in Computer Science from TAU; he holds two Ph.D.s: in Computer Science and in Medical Science both from TAU. He was a Safra Postdoctoral Fellow in the School of Computer Science and the Department of Molecular Microbiology and Biotechnology at TAU, and a Koshland Postdoctoral Fellow in the Faculty of Mathematics and Computer Science in the Department of Molecular Genetics at the Weizmann Institute of Science, Rehovot, Israel. In 2011, he joined the Department of Biomedical Engineering, TAU, where he received the Minerva Arches Award and is currently an Associate Professor. In 2013 he co-founded SynVaccine Ltd, a finalist in the Falling-Walls start-up competition that provides the first fully integrated computer-aided design and manufacturing (CAD/CAM) system for synthetic, rationally designed viruses. His research interests fall in the general areas of computational systems and synthetic biology. In particular, he works on deciphering, computational modeling, and engineering of gene expression.
