Abstract: "Professor Littlewood, when he makes use of an algebraic identity, always saves himself the trouble of proving it; he maintains that an identity, if true, can be verified in a few lines by anybody obtuse enough to feel the need of verification." (Dyson [Dy]).

Nowadays obtuse mathematicians can use computer algebra. Littlewood's dictum is obvious for finite algebraic identities like $(a+b)^3 = a^3+3a^2b+3ab^2+b^3$. In this paper, identities are classified into three classes: Real time-Littlewoodian, Zillion years-Littlewoodian, and Non-Littlewoodian. I suggest a research program whose purpose will be to classify identities, and families of identities, into these classes, and to try and enlarge the family of real-time Littlewoodian identities by devising efficient algorithms.

*Supported in part by NSF grant DMS-8800663

1. Introduction

David Blackwell once said that in order for a result to be interesting, it is not enough that it be new. For example, if one takes any two ten-digit numbers and multiplies them together, then the resulting identity is very probably a new result, but it is uninteresting. In any case, it is unnecessary nowadays to prove a result like "$123 \times 234 = 28782$", because it clearly belongs to a class of identities for which there is a well known verification algorithm. This algorithm of multiplication of two integers written in decimal notation is known to any four-grader is programmed into every calculator (for integers whose product has up to ten digits). Furthermore, in most computer algebra systems, one can multiply integers with an arbitrary number of digits, where the limit depends on the available memory of the computer.

So let us make the following definition:

Definition: An identity is *Littlewoodian* if it clearly belongs to a class of identities for which there is a known and programmable algorithm for determining the truth of the identity.

For example any identity like "$123 \times 234 = 28782$" is obviously Littlewoodian, as are finite algebraic identities like

$$(a+b)^4 = a^4 + 4a^3b + 6a^2b^2 + 4ab^3 + b^4.$$

Of course being Littlewoodian is time-dependent, and it is not enough that there *is* an algorithm, we must know how to perform it. It is conceivable that one can prove that a class of identities is intrinsically non-Littlewoodian, in analogy with Matijasevic's solution of Hilbert's tenth problem.

Consider the identity

$$(100^{(100^{100})}+1) \times (100^{(100^{100})}-1) = 100^{2(100^{100})}-1,$$

where it is assumed that the integers are spelled out in decimal notation, with $2(100^{100})$ digits. Although this identity is certainly Littlewoodian, it will take a zillion years, and zillion bytes of memory to perform. Such an identity I call *Zillion years Littlewoodian*. Of course any moderately smart human or artificially smart machine will recognize the above identity as a special case of the algebraic identity $(a+1)(a-1) = a^2 - 1$, which in itself is Real-time Littlewoodian, but this is not allowed, because finding the right generalization is not a purely mechanical operation in general.

The notion of "Real time-Littlewoodian" is also time dependent, because any day there may be a better algorithm. However it is conceivable that a class of identities be declared intrinsically zillion years-Littlewoodian, in analogy with the notion of intractableness in computer science.

Once a class of identities has been declared Littlewoodian, the human mathematician is far from superseded. We still need human mathematicians to conjecture nice identities, relate them to other branches of mathematics, and give proofs with insight, that explain *why* the identity is true. This insight will often show us how to generalize it to an identity that is non-Littlewoodian. The purpose of the computer is to save humans the dreadful task of devising proofs that Hardy called scornfully "essentially verifications", and concentrate on trying to find insightful proofs.

2 Quiz

For each of the following identities, state whether the identity is Real time-Littlewoodian, Zillion years-Littlewoodian, or Non-Littlewoodian. Answers to this quiz are given in the next section.

1 (Euler)

$2^{2^5} + 1 = 641 \times 670041.$

2 (Lander and Parkin [L-P])

$$27^5 + 84^5 + 110^5 + 133^5 = 144^5.$$

3

a)(Leonardo of Pisa)

$$(a^2 + b^2) \times (c^2 + d^2) = (ac + bd)^2 + (ad - bc)^2.$$

b.(Euler)

$$(a^2 + b^2 + c^2 + d^2) \times (A^2 + B^2 + C^2 + D^2) =$$
$$(aA + bB + cC + dD)^2 + (aB - bA - cD + dC)^2 + (aC + bD - cA - dB)^2 + (aD - bC + cB - dA)^2.$$

4

$$\sum_{i=1}^{N} n^3 = (N(N+1))^2/4.$$

5

$sin(x+a) = sinxcosa + cosxsina.$

6 (Cassini)

Let F_n be the Fibonacci numbers defined by $F_0 = 0$, $F_1 = 1$, and $F_n = F_{n-1} + F_{n-2}$, then

$$F_{n+1}F_{n-1} - F_n^2 = (-1)^n.$$

7

Let $b(n)$ be the number of complete binary trees with n leaves, and $t(n)$ be the number of ordered trees with n vertices, then $b(n) = t(n)$.

8

Consider the lattice

$$L(n,2) := \{(a_1, ..., a_n); 2 \geq a_1 \geq ... \geq a_n \geq 0\}.$$

The following chains ($0 \leq 2i \leq n$) constitute a symmetric chain decomposition of $L(n,2)$.

$$C_i^{(n)} := 2^i \to 2^i 1 \to ... \to 2^i 1^{n-2i} \to 2^{i+1} 1^{n-2i-1} ... \to 2^{n-i}.$$

9

a)For all square matrices A,B, of size $n \leq 9$, $det(AB) = det(A)det(B)$.

b)For all square matrices A,B, of size $n = 9000$, $det(AB) = det(A)det(B)$.

c) For all square matrices of arbitrary size n, $det(AB) = det(A)det(B)$.

10 (Amitsur-Levitski)

For an arbitrary n, let $A_1, ..., A_{2n}$ be $2n$ square $n \times n$ matrices, then:

$$\sum_{\pi \epsilon S_{2n}} sgn(\pi) A_{\pi(1)} ... A_{\pi(2n)} \equiv 0.$$

11 (Dyson)

a) The constant term of

$$[(1-x/y)(1-y/x)(1-x/z)(1-z/x)(1-y/z)(1-z/y)]^a$$

is $(3a)!/a!^3$.

b) The constant term of

$$\prod_{1\leq i\neq j\leq 1000}(1-\frac{x_i}{x_j})^a$$

is $(1000a)!/a!^{1000}$.

c) (Dyson's conjecture, see [An]) the constant term of

$$\prod_{1\leq i\neq j\leq n}(1-\frac{x_i}{x_j})^a$$

is $(na)!/a!^n$.

12 (Omar Qayam)

a)

$$(x+y)^3=x^3+3x^2y+3xy^2+y^3.$$

b)

$$(x+y)^n=\sum_{i=0}^{n}n!x^ky^{n-k}/(k!(n-k)!).$$

c)

$$(x_1+...x_m)^n=\sum_{k_1+...+k_m=n}n!x_1^{k_1}...x_m^{k_m}/(k_1!...k_m!).$$

13

a) ([Po])

$$\sum_{n=1}^{N}\frac{1}{n^3}-\frac{5}{2}\sum_{n=1}^{N}\frac{(-1)^{n-1}}{n^3\binom{2n}{n}}=\sum_{k=1}^{N}\frac{(-1)^k}{2k^3\binom{N+k}{k}\binom{N}{k}}.$$

b)

$$\sum_{n=1}^{\infty}\frac{1}{n^3}=\frac{5}{2}\sum_{n=1}^{\infty}\frac{(-1)^{n-1}}{n^3\binom{2n}{n}}.$$

14 (Rogers-Ramanujan)

a)

$$\sum_{n=0}^{\infty} \frac{q^{n^2}}{(1-q)...(1-q^n)} = \prod_{i=0}^{\infty} 1over(1-q^{5i+1})(1-q^{5i+4}).$$

b) ([Br])

$$\sum_{r=0}^{n} \frac{q^r sup2}{(q)_r (q)_{n-r}} = 1 + \sum_{r=1}^{n} \frac{(-1)^r q^{(5r^2-r)/2}(1+q^r)}{(q)_{n-r}(q)_{n+r}}.$$

3 Answers to the Quiz

Real time-Littlewoodian : 1-8,9a, 11a, 12a, 12b, 13a, 14b.

Zillion years-Littlewoodian : 9b, 11b.

Non-Littlewoodian : 9c,10,11c,12c,13b,14a.

4 Discussion

1and **2** :

These are examples of interesting numerical identities. 1) gives a refutation of Fermat's conjecture that $2^{2^n}+1$ is always a prime, and 2) refutes Euler's conjecture that it is impossible to express a fifth power as a sum of four perfect fifth powers. A formal proof of these identities will involve writing all the integers as a combination of powers of 10, invoking the associative and distributive laws, and then using the 100 "lemmas" that comprise the multiplication table and the 100 lemmas that constitute the addition table. Since arithmetic with specific integers is so much part of our culture, it would not occur to anyone to give a proof of a statement like 2), and the proof is considered routine by a general consensus.

3:

Way back in 1202, when *Liber Abaci* first appeared, identity 3a) was a deep theorem, and there were very few people who understood its proof. Nowadays this is a routine exercise that has the same epistemological stature as $9 \times 11 = 99$. But although routine, it is an important identity in number theory, as it implies the non-trivial fact that the product of two integers that are expressible as a sum of two squares is itself a sum of two squares. Similar remarks apply to identity 3b), which implies that if one can show that every prime is expressible as a sum of four squares, then every integer can be so expressed.

Although the proofs of 3a) and 3b) are completely routine, they are nevertheless elegant identities, and one may want to understand *why* they are true, as opposed to *whether* they are true. One such explanation is that for two complex numbers $z_1 = a + ib$, and $z_2 = c + id$, $|z_1 z_2| = |z_1||z_2|$. The analogous identity in the quarterions gives 3b). These observations were perhaps the motivation to Gauss's discovery of the Gaussian integers and to Hamilton's discovery of the quarterions.

4:

Any identity of the form

$$\sum_{n=1}^{N} p(n) = q(N),$$

with p and q polynomials, is routinely verifiable, since it is equivalent to

$$q(N) - q(N-1) = p(N).$$

Unfortunately, many inane identities of this kind are assigned to students , expecting them to use mathematical induction. Many students who do not understand mathematical induction "prove" this identity by plugging in a few values. They are not that wrong. For example, in order to prove identity 4) all we need is check it in 5 different values, say $N = 0, 1, 2, 3, 4$, since both sides are polynomials of degree 4.

5:

Trigonometric identities are feared and hated by many a high school student. Using $cosx = (e^{ix} + e^{-ix})/2$ and $sinx = (e^{ix} - e^{-ix})/2i$, they are all routine, and indeed trigonometric simplifications are built-in into most computer algebra systems.

6: Writing the Fibonacci numbers in terms of Binet's formula, identities like 6) are trivially verifiable, as are all identities involving sums and products of Fibonacci numbers, or more generally, solutions of constant coefficients homogeneous linear recurrences.

7:

Thanks to the work of the Lothargian school (Schutzenberger, Foata, Viennot and their students), many combinatorial sequences are known to have generating functions that are algebraic formal power series. It is by now a routine matter to find the equation satisfied by such a generating function and to see whether two such generating functions are equivalent. In fact it should be possible to find *a priori* bounds for the order of the equation satisfied by the generating function, as well as bounds for the degrees of the coefficients. Then it should be possible to find an *a priori* integer N such that if the two combinatorial sequences of the problem are equal up to N, then they are identical. It follows that many theorems on trees, and on two and three dimensional lattice walks are either routine or routineable. Of course it is nice to have *nice* proofs , preferably bijective, to prove such results, but if the proof is going to be ugly it may just as well be done by computer.

8:

This statement is not only "routine" in the colloquial sense of the word, but is also technically routine, since it can be easily encoded in terms of an identity involving rational functions of a *fixed* number of variables.

Consider

$$M(n) := \{(a_1, ..., a_m); for some m \geq 0, n \geq a_1 \geq a_2 \geq ... \geq a_m \geq 0\}.$$

(Note that we allow some trailing zeroes).

Introduce the commuting indeterminates $x_1, ..., x_n$ and t, and define the weight

$$weight(a_1, ..., a_m) = x_{a_1}...x_{a_m}t^{m,}$$

with the convention that $x_0 = 1$. The subset of $M(n)$ of partitions of length m (allowing zeroes) can be easily identified with Young's lattice $L(m, n)$. It is easily seen that the total weight of $M(n)$ (i.e. the sum of the weights is):

$$(1-t)^{-1}(1-x_1t)^{-1}...(1-x_nt)^{-1}.$$

The total weight of the chains C_i , for a fixed n is

$$(x_2^i + x_2^i x_1 + ... + x_2^{n-2i} + x_2^{i+1}x_1^{n-2i-1} + ...x_2^{n-i})t^{n,}$$

which is some (simple) rational function, and summing with respect to n yields geometric series that are easily summed. Thus the statement that the chains $C_i^{(n)}$ cover $L(2, n)$, for every n, is equivalent to a simple identity among rational functions. Of course it is obvious by inspection that $C_i^{(n)}$ are symmetric chains.

By the same token, the verifications of West's[We] constructions of a symmetric chain decomposition of L(4,n) and Riess's [Ri] for L(3,n) and L(4,n) are purely routine and could have been omitted. This does not take away from their achievements, because the hard part was to find the constructions. But once found, the verification is a purely routine matter and two pages of the European Journal of Combinatorics could have been spared.

On the other hand, a symmetric chain decomposition of L(m,n) for general m *and* n is not going to be routinely verifiable, at least not at present. Neither is O'Hara's[O'h] recent magnificent symmetric chain decomposition of the "complete" version of L(m,n) where any two partitions with different ranks are related.

9:

There are many identities in matrix algebra, of which 9) is one of the simplest. Writing the matrices in generic form, the statement $det(AB) = det(A)det(B)$, for a fixed n is nothing but a finite algebraic identity, but of course for $n = 9000$ we would have more than $9000!^2$ terms ! Of course identity 9c), for general n, is non-Littlewoodian (at least today).

10:

This is the celebrated Amitsur-Levitski identity, that was given an elegant proof by Rosset [Ro]. For general n it is non-Littlewoodian.

11:

Identity 11c) is Dyson's ex-conjecture, that was proved by Wilson and Gunson and that was given a short and elegant proof by Good(see [An]). For general n this is certainly non-Littlewoodian, but for $n = 3$ (identity 11a) and for $n = 1000$ (11b) it is real time-Littlewoodian and zillion years-Littlewoodian respectively. This follows from my approach ([Ze]) to special functions identities that is based on I.N.Bernstein's theory of holonomic systems.

12:

No one would argue with the assertion that 12a) is real time-Littlewoodian. That the binomial theorem is real time-Littlewoodian follows from my above mentioned approach ([Ze]), but the multinomial theorem, that involves an *indefinite* number of variables is not covered by this theory, and is thus non-Littlewoodian at present.

13:

Identity 13b) was the starting point of Apery's incredible proof of the irrationality of $\zeta(3)$ ([Po]). At present such identities that state the equality of two infinite hypergeometric series (and whose summands only depend on the index of summation, and not on an auxiliary parameter) are non-Littlewoodian. On the other hand, 13b), which is the "finite form" of 13a), is nothing but a binomial coefficients identity and is certainly real time-Littlewoodian. Note that from a human point of view, 13b) is a trivial consequence of 13a), upon taking $n \to \infty$, and thus 13a) is "deeper" and more general.

14:

This final example illustrates the q-analog of the point made in the previous example. 14a) is one of the Rogers-Ramanujan identities, and involves the equality of an infinite q-hypergeometric series and an infinite q-hypergeometric product. Since we do not have any extra parameters to provide elbow room, it is, at present, non-Littlewoodian. On the other hand, the finite form of this identity, 14b) (that implies 14a upon taking $n \to \infty$ and using the Jacobi triple product identity) is nothing but a q-binomial coefficients identity , and as such is real time-Littlewoodian ([Ze]). Given an infinite q-hypergeometric identity we still need, at present, a Schur, an Andrews, or a Bressoud to come up with a *conjectured* finite form, that my program can then do.

5 An Open Problem

It would be nice if identities like 13b) and 14a) would be provable by computer. Consider an identity

$$\sum_{i=1}^{\infty} a(n) = \sum_{i=1}^{\infty} b(n), \qquad (*)$$

where $a(n)$ and $b(n)$ are hypergeometric sequences, i.e., there exist polynomials $P(n), Q(n), R(n), S(n)$ such that

$$a(n+1)/a(n) = P(n)/Q(n), b(n+1)/b(n) = R(n)/Q(n).$$

It would be interesting to develop a decision procedure, in the style of [Go], that will decide whether an identity like (*) is true or false.

Consider

$$c(N) := \sum_{i=1}^{N} (a(n) - b(n)).$$

The statement (*) is equivalent to the fact that $c(N) \to 0$ as $N \to \infty$. It is not hard to find a second order linear recurrence equation (with polynomial coefficients) satisfied by $a(n) - b(n)$, and

hence a third order linear recurrence equation satisfied by $c(N)$. The problem of deciding whether identities of the form (*) are true would follow from the following more general problem:

Problem

Given a homogeneous linear recurrence with polynomial coefficients:

$$p_0(n)a(n) + p_1(n)a(n-1) + ... + p_i(n)a(n-i) + ...p_K(n)a(n-K) = 0,$$

and K initial conditions : $a(0), ..., a(K-1)$*, decide whether or not the solution* $a(n)$ *of the equation , subject to the initial conditions, has the property that* $a(n) \to 0$ *as* $n \to \infty$*.*

The Birkhoff-Trijinski method (resurrected in [Wi-Ze]) enables us to find the complete asymptotics of the *dominant* solution of a linear recurrence equation. What we need is some way to handle the asymptotics of an arbitrary solution, under prescribed initial conditions. On the other hand we are not asking for *complete* asymptotics but only whether or not it tends to zero.

q-Analogously, one may pose the q-problem, that will enable our machines to prove Rogers-Ramanujan style identities, and will free us humans to prove $multi - variate$ extensions, like the multi-variate extensions of Andrews, Gordon, and Bressoud (see [An], (3.45), (3.46)).

q-Problem

Given a homogeneous linear recurrence with polynomial coefficients (in q and q^n*):*

$$p_0(q^n, q)a(n) + p_1(q^n, q)a(n-1) + ... + p_i(q^n, q)a(n-i) + ... + p_K(q^n, q)a(n-K) = 0,$$

and K initial conditions : $a(0), ..., a(K-1)$*,(certain formal power series in q) decide whether or not the solution* $a(n)$ *of the equation , subject to the initial conditions, has the property that* $a(n) \to 0$ *as* $n \to \infty$ *, in the sense of formal power series in q.*

I am offering 50 dollars for a solution of the problem, and an additional $(1-q^{50})/(1-q)$ dollars for a solution of the *q-problem* (where, for this one, I adopt the analyst's custom of taking $|q| < 1$).

6 Concluding Remarks

The computer is here to stay, for better or for worse, and as Marshal McLuhan has taught us, it will shape our practices, problems, ways of thinking and even our tastes. This was put beautifully by Ruelle[Ro]:

My guess is that, within fifty or hundred years (or it might be one hundred and fifty) computers will successfully compete with the human brain in doing mathematics, and that their mathematical style will be rather different from ours. Fairly long computational verifications (numerical or combinatorical) will not bother them at all, and this should lead not just to different sorts of proofs, but more importantly to different sorts of theorems being proved.

Most mathematicians nowadays still consider computer-assisted proofs as "cheating", and a priori "ugly" and "not giving any insight", as was manifested by the cold and hostile reception of Appel and Haken's marvelous tour-de-force. But I am not worried for Appel and Haken. In a hundred years, their proof will be considered as elegant as any human proof, and its only drawback will be the fact that it involves *too much* human effort.

In the future, given a "conjecture", one would try to embed it into a class of statements having a given format, and then develop an effective method for deciding the truth of the statements in this class, or whether it is "undecidable" or "intractable".

Given an algorithm to decide the truth of such a class of statements, nobody would care if the computer-generated proof, in every given instance, is long and ugly, and this is just as well. What is perhaps sad is that nobody would probably care whether the algorithm itself is elegant or not, and everything will be judged by its computational complexity. Be that as it may, let us enjoy the present exciting transition era, where we can both enjoy the rich human heritage of the past , as well as witness the first crude harbingers of the marvelous computer-mathematics revolution of the late 21^{th} century.
