

Solution of American Mathematical Monthly #11929 (Oct. 2016, Proposed by Donald Knuth)

Justin SEMONSEN

In [K], Donald Knuth proposed the following intriguing problem.

11929 Proposed by Donald Knuth, Stanford University, Stanford, CA. Let a_n be the number of ways in which a rectangular box that contains $6n$ squares tiles in three rows of length $2n$ can be split into two connected regions of size $3n$ without cutting any tiles. Thus $a_1 = 3, a_2 = 19, a_3 = 85$. Taking $a_0 = 1$, find a closed form for the generating function $A(z) = \sum_{n=0}^{\infty} a_n z^n$. What is the asymptotic nature of a_n as $n \rightarrow \infty$?

Ans.

$$A(z) = \frac{z(2z^6 + 15z^5 + 21z^4 - 38z^3 + 40z^2 - 9z + 1)}{(z-1)^3(z^2 + 4z - 1)^2} + \frac{(1-3z)^2}{(1-4z-z^2)^2} \cdot (1-4z)^{-\frac{1}{2}} .$$

The asymptotic of a_n , to order five is:

$$a_n \asymp \frac{16}{\sqrt{\pi}} \cdot \frac{4^n}{\sqrt{n}} \cdot \left(1 - \frac{169}{8} n^{-1} + \frac{113713}{128} n^{-2} - \frac{54662275}{1024} n^{-3} + \frac{136066657419}{32768} n^{-4} - \frac{103820177963271}{262144} n^{-5} + O\left(\frac{1}{n^6}\right) \right) .$$

Proof: We first need a **crucial lemma**

Lemma: Let $f(r, w)$ be the number of configurations (with the white and black areas both connected) with r columns and w white squares (and hence $3r - w$ black squares), then the bi-variate generating function

$$F(x, y) = \sum_{r=0}^{\infty} \sum_{w=0}^{3r} f(r, w) x^r y^w$$

is given by the *rational function*

$$F(x, y) = \frac{Top(x, y)}{Bot(x, y)} ,$$

where the numerator, $Top(x, y)$, is given by

$$\begin{aligned} Top(x, y) = & -3x^4y^2 - x^2y^6 + 4x^4y^4 + 12x^4y^7 + 8x^6y^7 + 25x^6y^8 + 8x^6y^{11} - 6x^2y - 6x^2y^2 \\ & + 25x^6y^{10} - 6x^2y^4 - 6x^2y^5 - 3x^4y^{10} - 2x^4y^9 + 4x^4y^8 + 2x^4y^6 + 12x^4y^5 - 6x^2y^3 \\ & + x^4 - x^2 - 2x^4y^3 + 6x^6y^{12} + 28x^6y^9 + 10x^{12}y^{21} + 4x^{10}y^{21} - 5x^{12}y^{20} + 12x^{12}y^{22} \\ & + 4x^{12}y^{23} - 5x^{12}y^{16} + x^8y^8 - 28x^8y^{11} - 9x^8y^{10} - 42x^8y^{12} + 6x^6y^6 \\ & - 6x^6y^5 - 6x^6y^{13} - 28x^8y^{13} - 9x^8y^{14} - 8x^6y^{14} - 7x^8y^6 + 32x^{10}y^{11} + 35x^{10}y^{12} \\ & - 8x^6y^4 - 2x^8y^7 - 2x^6y^{15} + x^8y^{16} - 25x^{10}y^{14} - 38x^{10}y^{15} + 12x^{10}y^{13} + 35x^{10}y^{18} \end{aligned}$$

$$\begin{aligned}
& -28x^{12}y^{18} - 22x^{12}y^{19} + 32x^{10}y^{19} + 12x^{10}y^{17} - 25x^{10}y^{16} - 2x^6y^3 - 7x^8y^{18} \\
& -2x^8y^{17} - 4x^8y^{19} + 17x^{10}y^{20} - 22x^{12}y^{17} + x^4y^{12} - x^6y^{16} + 17x^{10}y^{10} \\
& -x^6y^2 - 4x^{14}y^{21} - 2x^{14}y^{20} \\
& -2x^{14}y^{22} + 4x^{10}y^9 - 4x^8y^5 + 12x^{12}y^{14} + 10x^{12}y^{15} + 4x^{12}y^{13} \quad ,
\end{aligned}$$

and the denominator, $Bot(x, y)$ is given by

$$2(x+1)^2(xy^2+1)(xy+1)(xy^3+1)^2(xy+xy^2+1)(x-1)^2(xy^2-1)(xy^3-1)^2(xy-1)(xy+xy^2-1) \quad .$$

Sketch of proof: We set-up a “grammar” with ten states, corresponding to how a column can be colored, and connectivity considerations, set-up a system of ten equations and ten unknowns, add the solutions up, and get the above monster rational function. \square

Since $a_n = f(2n, 3n)$, we have

$$A(z) = \sum_{n=0}^{\infty} f(2n, 3n)z^n \quad ,$$

is a ‘*slanted diagonal*’ of the rational function $F(x, y)$ of ‘slope’ $3/2$. By a famous theorem of Hillel Furstenberg [F], it is guaranteed to be an algebraic formal power series, that can be easily found by taking a certain residue, but we prefer to crank-out sufficiently many terms (40 suffice) of a_n , using $F(x, y)$, and fit them into an algebraic equation for $A(z)$, e.g. using Maple’s `gfun[listtoalgeq]` command. We get that $A(z) = A$ is a solution of the quadratic equation

$$\begin{aligned}
& -10z + 1 - 110z^3 + 178z^5 - 618z^6 + 108z^{10} + 862z^7 - 485z^8 + 88z^9 + 16z^{11} + 46z^2 + 116z^4 \\
& -2z(4z-1)(2z^6 + 15z^5 + 21z^4 - 38z^3 + 40z^2 - 9z + 1)(z-1)^3 A \\
& + (4z-1)(z^2 + 4z - 1)^2(z-1)^6 A^2 = 0 \quad .
\end{aligned}$$

Using the quadratic formula, taking the right solution (that is a formal power series with positive coefficients), and simplifying, yields the closed form solution stated above for $A(z)$. Expanding $(1-4z)^{-1/2}$ by the binomial theorem, using Stirling, and performint routine manipulations (all done automatically by Maple) produces the stated asymptotic formula for a_n .

Supporting Maple code can be gotten from
