Fréchet: Is there a universal complete separable metric space?

*In dieser letzten Hinsicht ist es Urysohn gelungen einen (in Ihrem Sinne) vollständigen metrischen Raum mit abzählbarer dichter Teilmenge, der einen jeden anderen separablen metrischen Raum isometrisch enthält und außerdem **eine recht starke Homogenitätsbedingung** füllt, zu konstruieren; letzterer besteht darin, daß man den ganzen Raum (isometrisch) so auf sich selbst abbilden kann, dass dabei **eine beliebige endliche Menge M in eine ebenfalls beliebige, der Menge M kongruente Menge M_1 übergeführt wird.** [Alexandrov to Hausdorff (Cf. Hušek 2006)]*

 - *Finite, classified by Cameron*
 - *Diameter ≤ 2 , classified by Lachlan/Woodrow*
 - *Tree-like, described by Macpherson in the locally finite case*
- *Generic type:*
 - $\Gamma_{K,C,S}^\delta = \lim \mathcal{A}_{K,C,S}^\delta$ (new);
 - $\Gamma_{a,n}^\delta$ (“antipodal” variation)

Non-generic: Defined in terms of the local structure (neighbors of 1 or 2 vertices).

Summing Up

① If $C \leq 2\delta + K_1$:

① If $r^- \geq K_1$ then take $d(a_1, a_2) = r^-$.

Otherwise:

② If $C' = C + 1$ then:

① If $r^+ \leq K_2$ then take $d(a_1, a_2) = \min(r^+, \tilde{r})$

② If $r^- < K_1$ and $K_2 < r^+$ then take $d(a_1, a_2) = \tilde{r}$ if $\tilde{r} \leq K_2$
and $d(a_1, a_2) = K_1$ otherwise.

③ if $C' > C + 1$ then:

① If $r^+ < K_2$ then take $d(a_1, a_2) = r^+$;

② If $r^- < K_2 \leq r^+$ then take

$$d(a_1, a_2) = \begin{cases} K_2 - 1 & \text{if there is } v \in A_0 \\ & \text{with } d(a_1, v) = d(a_2, v) = \delta \\ K_2 & \text{otherwise} \end{cases}$$

② And otherwise ...

- The non-generic are all classified.
- The catalog is complete in diameter 3 (joint with Amato, Macpherson).
- The catalog is (conditionally) complete for bipartite graphs, in an inductive setting.

Summing Up

(with Shelah)

Fix a finite constraint set \mathcal{C} and look for a universal countable \mathcal{C} -free graph.

Example

if \mathcal{C} is closed under homomorphism, then there is a universal countable \mathcal{C} -free graph.

Theorem (Nešetřil)

The Ramsey Property holds, with a generic linear order and a suitable base language. So $\text{Aut}(\Gamma)$ is extremely amenable.

General Expectation: Strong requirements on \mathcal{C} , but interesting examples.

Conjecture (1 constraint)

If there is a universal \mathcal{C} -free graph then the following hold:

- *All blocks of \mathcal{C} are complete;*
- *After removal of some trivial blocks, the tree of blocks is a path.*

Thus there is a striking contrast between finite and infinite graphs: while „almost all“ finite graphs are asymmetric, „almost all“ infinite graphs are symmetric. [Erdős/Rényi 1963]
