

# Trees: Math 454 Lecture 11 (7/17/2017)

Cole Franks

July 17, 2017

Some of these notes follow sections 5.1 and 5.6 of Keller and Trotter, which you can find here:

[http://www.rellek.net/book/ch\\_graphs.html](http://www.rellek.net/book/ch_graphs.html).

More is in Brualdi 11.5. We also talked a bit about isomorphism today; some of that stuff can be found in Lecture 10.

**Remark 0.1.** One key take-away from the definition of isomorphism is that any property of graphs which doesn't depend on the names of the vertices is preserved under isomorphism. For example, if  $G$  and  $H$  are isomorphic, then the property "contains a copy of  $C_3$ " is satisfied by  $G$  if and only if it is satisfied by  $H$ . A non-example of such a property is the property " $ab$  is an edge of  $G$ ", which clearly depends on the labels of vertices, so we needn't have  $ab$  an edge of  $H$  even if  $G$  and  $H$  are isomorphic. We'll define containment formally later in these notes.

## 1 Subgraphs

**Definition 1.1** (Subgraph). If  $G = (V, E)$  is a graph, then  $H = (W, F)$  is a subgraph of  $G$  if  $W \subset V$  and  $F \subset E$ . Sometimes we say  $G$  *contains*  $H$ . If  $G$  contains a subgraph isomorphic to  $H$ , we say  $G$  *contains a copy* of  $H$ .

**Example 1.** The graph

contains the subgraph

and also the subgraph

**Definition 1.2** (Acyclic). A graph  $G$  is *acyclic* if it contains no cycles.

**Example 2.** An acyclic graph:

## 2 Connectivity

**Definition 2.1** (Connected, Connected Component). A graph  $G = (V, E)$  is *connected* if for any pair of distinct vertices  $x$  and  $y$ ,  $G$  contains a path with  $x$  and  $y$  as endpoints.

Intuitively, you can get from any place in the graph to another by walking along the edges. A graph that is not connected is said to be *disconnected*. If  $G$  is a graph, then a *connected component*  $C$  of  $G$  is a maximal connected subgraph of  $G$ . That is, you can't add any more vertices to  $C$  and still have it be a connected subgraph of  $G$ .

A connected component is everything you can get to from a particular vertex in  $G$  by walking on the edges.

A connected graph:

A disconnected graph:

**Theorem 2.1.** A connected graph  $G$  with  $n$  vertices has at least  $n - 1$  edges.

*Proof.* Think about this by adding the edges of  $G$  one at a time. Before we have added any, there are  $n$  components. Each time we add a new edge, we can decrease the number of components by at most one (either we join two, or we don't!). Thus, we need to add at least  $n - 1$  edges to get one component (i.e., a connected graph).  $\square$

## 3 Trees

Trees are the “smallest” connected graphs.

**Definition 3.1.** A connected, acyclic graph is called a *tree*.

**Example 3.** A tree:

**Definition 3.2.** The *neighborhood*  $N(v)$  of a vertex  $v$  is all vertices adjacent to  $v$ .

**Remark 3.1.** Let  $T$  be a tree. Let's try to draw  $T$ . Start at some arbitrary vertex  $r$ . Look at its neighbors; draw them below  $r$ . For each of the neighbors, look at their neighborhoods other than  $r$ . Those neighborhoods can't intersect, because otherwise there would be a cycle. Thus, we can draw their neighborhoods (other than  $r$ ) below them. We can do this for the vertices we just drew; because there are no cycles, we will be able to place the new neighborhoods directly below the corresponding existing vertex. Continuing this process gives a nice (upside down) tree-like picture.

**Example 4.** A better way of drawing the last tree we saw is

### 3.1 Important properties of trees

**Theorem 3.1.** (*Big tree theorem*) Let  $T$  be a graph on  $n$  vertices. The following are equivalent.

1.  $T$  is a tree.
2.  $T$  is connected but removing any edge from  $T$  results in a disconnected graph.
3.  $T$  is connected and has exactly  $n - 1$  edges.

4.  $T$  is acyclic and has exactly  $n - 1$  edges.

**Proof of 2 using 1:** Assume  $T$  is a tree, so it is connected and acyclic. Consider an edge  $xy$  of  $T$ . If removing  $xy$  doesn't connect the graph, then there is a path between  $x$  and  $y$  that doesn't use  $xy$ . Adding  $xy$  back in gives a cycle in  $T$ , so  $T$  must contain a cycle; this is a contradiction.

**Proof of 3 using 2 and 1:** Let's do this by induction on  $n$ , the order of the tree. A single vertex is a tree and has 0 edges, so the base case  $n = 1$  holds. Let  $T$  be a tree with  $n \geq 2$  vertices, then there must be an edge  $xy$  or else the graph cannot be connected.  $T' = (V, E \setminus \{xy\})$  must have two components, because by the last argument we know there is at most two and there cannot be just one component by part 1 of the Theorem. Thus,  $T'$  has two components, each of which is a tree. Say one of the components has  $1 \leq k \leq n - 1$  vertices; then the number of edges in these two trees is  $(k - 1) + (n - k - 1) = n - 2$  by induction. When we include  $xy$ , we get  $n - 1$ .

**Proof of 2 using 3 :** If  $T$  is connected but has  $n - 1$  edges, then removing any edge disconnects it by Theorem 2.1. Hence 2 holds.

**Proof of 1 using 2:** Suppose  $T$  satisfies 2 but  $T$  has a cycle. Then removing some edge of this cycle does not disconnect  $T$ , a contradiction. Hence  $T$  is acyclic and connected, and so it is a tree.

**Proof of 4 using 3 and 1:** Easy.

**Proof of 1 using 4 and the equivalence of 1 and 3:** If  $T$  is acyclic, each of the  $k$  connected components of  $T$  must be trees. By the equivalence of 1 and 3 which we have already shown, if the components have  $n_1, \dots, n_k$  vertices, then they have  $n_1 - 1, \dots, n_k - 1$  edges. Thus,  $T$  has  $(n_1 - 1) + \dots + (n_k - 1) = n - k$  edges, so  $k = 1$ , implying  $T$  is connected. Thus  $T$  is a tree.
